THE Governor of Hong-Kong (Sir HENRY BLAKE, G.C.M G.) has been not only interesting himself in the eradication of plague but has taken steps to give a well-considered scheme of his own a practical trial. Sir HENRY BLAKE, in a memorandum which he has written upon the subject, states that he attributed the "dumping" of bodies dead from plague in the streets and on hill sides of the colony "to the dread of the disinfecting process as carried out by the sanitary authorities." The plan adopted by the authorities consisted of (1) placing a policeman in charge of the plague-infected house; (2) detaining the inmates until their clothes are disinfected; and (3) disinfection of the house. Great dissatisfaction was caused amongst the Chinese in the city by these processes and to overcome some of the objections Sir HENRY BLAKE set about devising a plan more acceptable to the poorer inhabitants. Firstly, he nominated a committee for every health district to deal with the matter but bodies still continued to be "dumped." He then, after consultation with the Hon. J. M ATKINSON, M.B., principal civil medical officer, asked to have a block of houses in a plague-infected district handed over to him to be dealt with according to the following plan. He visited the locality with several members of the Colonial Government staff and several of the leading Chinamen. He called the people together and addressed them upon the necessity of personal cleanliness, the destruction of vermin, and the meaning of disinfection of clothing and of dwellings. To enable them to clean their houses he erected tanks for boiling a watery solution of Jeyes' fluid into which bed-boards and furniture could be dipped and he provided washhouses for both sexes. In the month of April, 1903, the process of cleansing the district was begun and in course of time 253 houses were systematically dealt with. Moreover, local hospitals were established in the district to which the patients were willingly transferred by their relatives and where the relatives were allowed to nurse them under the treatment of either European or Chinese medical men as preferred The outcome of these measures was that "dumping" of the dead bodies ceased, the disease practically disappeared, and early notification was expedited.

In addition to these practical steps Sir HENRY BLAKE fostered the scientific investigation of the general prevalence of plague in men and in animals. The question of the general infection of the community was investigated by Dr. W. HUNTER. He examined 110 specimens of blood from men, women, and children taken at random and found plague bacilli in 4·54 per cent. of the persons thus examined. Extending these figures proportionately to the inhabitants of the city, it would appear that some 8000 or 9000 persons had plague bacilli in their blood in whom there were neither signs nor symptoms of their being thus affected. In other words, chronic plague may exist in a plague-infected district amongst persons apparently well. Dr. W. J. R. SIMPSON had already shown that domestic animals suffer from chronic plague and Dr. HUNTER found flies, cockroaches, bugs, and the like, to be similarly infected. A further interesting fact was brought to light by Dr. HUNTER, namely, that in specimens of rice exposed for sale in the shops plague bacilli exist. Sir HENRY BLAKE recognises the fact that the unhygienic construction of Chinese dwellings and tenements is chief difficulty to be contended with in the ext tion of plague and in the existing circumstances, there he believes that the rigid observance of personal a household cleanliness is the only available method eradicating or limiting outbreaks of plague. His attempt to render cleanliness easy of accomplishment has been attended by excellent results and we hope to see the disease eliminated, or at all events reduced in virulence, by his well-timed interference on behalf of the colony.

Annotations.

"Ne quid nimis."

THE ST. BARTHOLOMEW'S HOSPITAL APPEAL.

Her Majesty the Queen has forwarded to the Lord Mayor of London a sum of £1000 to start the appeal which it is intended to make shortly to the public for funds for the new buildings and improvement of the present buildings of St. Bartholomew's Hospital. The Lord Mayor has sent the money to the treasurer of the hospital, Sir Trevor Lawrence. This gentleman, it will be remembered, was the proposer of the motion passed on Jan. 19th last appointing a committee of 15 members to inquire into the hospital affairs At the meeting of this committee of inquiry, which was held at the Mansion House on May 5th, the committee expressed the opinion that it was fully justified in appealing to the public for funds to enable it to utilise the land acquired from Christ's Hospital and to provide the new buildings urgently necessary to bring the hospital up to modern requirements in all respects. As the appeal is going to be made within a short time we can only express the hope that the great depression of the public funds and other stocks and shares and the general agitation over the fiscal question will not thwart and obscure the efforts for publicity and success which the appeal committee will make. We have received an advance proof of an article by Sir Henry Burdett to be published in the *Hospital*. He points out that the present site, together with the additional land recently purchased from Christ's Hospital, comprises an area of a little over six acres. In his opinion this area is insufficient to contain all the buildings required for the purposes of a modern hospital and, in addition, everything essential to the successful conduct of a great medical school. He proposes, to put the matter shortly, that in addition to the £350,000 which the Mansion House committee decided that the hospital should appeal for, a further £250,000 should be asked for in order to purchase more land from the governors of Christ's Hospital. Sir Henry Burdett's article includes a plan of the hospital as he would have it. According to this plan both the present residential college and the nursing home are eliminated from the present site, but Sir Henry Burdett does not say to where these two institutions are to be moved. We have authority for stating that the medical and surgical staff of St. Bartholomew's Hospital has always felt and said that the amount of land recently acquired is not sufficient for all that is wanted, as a large part of the new ground is to be taken up with the new nursing home. In the opinion of the staff the nursing home should be removed outside the actual hospital walls in the same manner as it has already been decided to remove the residential college In that case the staff considers that all that is likely to be required for many years to come could be arranged on the site now available. We have already expressed our opinion upon the various matters as to whether St. Bartholomew's Hospital should remain on its present site and as to whether it ought to appeal to the public for funds.[1] The hospital, like so many other metropolitan hospitals, benefits the country at large although primarily a City institution, and in the present circumstances it seems to us that whether or not it is decided to remove the nursing home and the residential college more land is a necessity. £600,000 represent without doubt a large sum, but we are sure that if the public, including all who are or have been at any time connected with St. Bartholomew's Hospital were convinced that by the expenditure of this sum the ancient foundation would be put upon firm ground for many years to come the money would not be long in forthcoming. The kindly gift of the Queen will without doubt give the movement a favourable start and it is to be hoped that at the meeting of the governors to be held on Nov. 5th the matter will be seriously considered and that those present will remember that the expenditure of an apparently large sum now will really prove an economy by making sufficient provision for future years.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE Lord Mayor of London, who is treasurer of the Hospital Sunday Fund, has received from Mr. George Herring the amount of £12,312 for the year 1903, in accordance with his most generous offer to add one-fourth to the total amount collected in each place of worship on Hospital Sunday in aid of the Fund. Mr. Herring's latest gift therefore represents £49,248 thus collected as against £46,300 in 1902. The total receipts of the Fund this year, including income from other sources and Mr. Herring's special gift, comes to £64,700, as against £62,669 in 1902 (an increase of £2031). We are quite sure that Mr. Herring is as glad as we are to see the demand on his pocket steadily growing and we can only add—long may he continue his beneficence and may he find many imitators.

THE ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.

THE annual dinner of this association took place on Oct. 23rd under the presidency of Mr. E. Climson Greenwood and was attended by members from all over the country. The proceedings of the afternoon meeting will be found at p. 1253. The President, in a half serious and half humorous speech, proposed the toast of "The Boards of Guardians." Although there were no guardians present (with the exception of Sir W. S. Church) they had among them men who were of more importance than the guardians—namely, the clerks to the boards of guardians. Mr. Henry List, in responding, said there was no reason why public vaccinators should not be appointed and paid by the local authorities in the same way as the registrars and superintendents of registration were appointed and paid. Mr. H. Stuart Sankey, L.C.C. (recorder for Faversham and standing counsel to the association), in proposing the toast of "The Visitors" said that the President had plunged them into a dismal gloom by bringing before their eyes the harrowing spectacle of the highly trained public vaccinator being trampled on by the brutal guardians and he had put before them a picture of the depths of poverty into which they had been plunged by the extremely inadequate fees which they were paid. He was, however, filled with admiration at the way in which they had all disguised their feelings that night. He next referred to the visitors present, including Sir W. S. Church, Dr. Dawson Williams, Dr. S. M. Copeman, Mr. D. B. Balding, J.P., Dr. A. G. Bateman, and Mr. E. W. D. Elsam. Sir W. S. Church, in responding, mentioned his connexion with the Imperial Vaccination League. They had to overcome the ignorance of the public with respect to vaccination. He recounted an interesting conversation he had had two years ago with Sir Harry Johnson whom he found to be a strong vaccinationist and who used the strongest language about anti-vaccinationists. He said he only wished he had them with him in Africa where he had seen whole tribes carried away by small-pox. The natives knew the value of vaccination and crowded round to be operated on when the mails arrived with a fresh supply of lymph. Mr. Balding and Mr. Elsam, honorary secretary to the National Vaccination Officers' Corporation, having responded other toasts followed. After the President had responded to the toast proposed by Mr. V. A. Jaynes, which was received with musical honours, a most enjoyable evening terminated.

THE PERIODIC FORM OF MELANCHOLIA AND OTHER MENTAL DISTURBANCES.

THE periodicity of certain forms of insanity has been recently the subject of special study by alienists. The late Dr. Krafft-Ebing in his recent text-book[1] refers to an extensive series of cases collected by him which serves to show the rôle of heredity in determining the attacks of the periodic insanities. In the *New York Journal of Nervous and Mental Disease* for September, Dr. Alfred Gordon, neurologist to the Jefferson Medical College, Philadelphia, refers to the fact that cases of periodic insanity are not frequently met with in asylums for the insane, though outside asylums they are not very rare, as a number of such cases have come under his observation. This is due to the fact that in the periodic insanities the attacks of mental derangement occur at limited and sometimes brief periods and that in the intervals between such attacks the patient is more or less free from mental disturbance. Cases of this sort are also important in a medico-legal sense since the question of responsibility for acts committed during the periods of such "attacks" may be raised in the law-courts and the defence of insanity may be set up. The view entertained by alienists a century ago that the intervals between the attacks must be of equal duration in cases of periodic insanity can now no longer be held. The records of cases published during the past half century and individual experience show that the duration of the interval varies. The periodic psychoses known are periodic melancholia, mania, paranoia, and circular insanity, in which definite maniacal and melancholic states alternate. Mania is often likely to occur in the periodic or recurrent form and melancholia comes next in order of frequency. Dr. Gordon refers to three cases of typical intermittent melancholia continuously observed by him during the previous four years. "The evolution of the disease as well as other features," he states, "are so different from the common type of melancholia that they deserve a special mention." He observed that in all of them there were no morbid symptoms (prodromes) immediately preceding the onset of each attack. While ordinary melancholia develops in an insidious and progressive manner so that the patient or his relatives cannot as a rule indicate the time when the state of depression exactly begins, in periodic melancholia of the intermittent type the onset is strikingly sudden. Feeling perfectly well a day before, the patient awakes in the morning with symptoms of sadness. Sometimes a local pain of the nature of facial neuralgia or cephalalgia of short duration is present at the beginning of the attack. As the onset is characterised by its suddenness the termination of an attack of periodic insanity is equally abrupt, while an attack of ordinary melancholia subsides slowly and very gradually. Of the cases recorded by Dr. Gordon the following is one. The patient was a married woman, aged 35 years, and had been through seven pregnancies. Her personal history showed that she suffered from mental "obsessions" at the age of 16 years and was always of a highly irritable disposition and that a sister and a grandmother suffered from insanity. In 1899, after her fourth confinement, in the midst of apparently perfect health, she suddenly became depressed and felt that she could not do her work, and when she commenced her work she had to discontinue it immediately. She worried over this because she could not do anything for her children—e.g., prepare their food, and finally she lost all interest in her household, in her husband, and in her children. This painful depression of spirits became associated with physical apathy and aversion to the sexual act. Her mind was dominated by sad ideas, and she gradually developed the delusion that she was unworthy to live and had been condemned to perish. The appetite was lost and wasting set in. The respiration was slow and superficial, the pulse was small and accelerated, and frequent pain was felt in the præcordial region. The blood showed marked deficiency of hæmoglobin and a distinct degree of leucocytosis (22,000 leucocytes per cubic millimetre). There were also present headache, partial insomnia, horrible dreams, and occasional visual hallucinations. The mental state just described remained almost unchanged for two months, except for occasional remissions lasting for a few hours. "At the expiration of two months, one morning the patient awoke in a calm and peaceful manner, called her children, began to caress them, and offered to prepare breakfast for the family." The mental faculties cleared up rapidly, interest in her surroundings and in herself was quickly restored, and the melancholic state entirely vanished. She became pregnant again and was in good health when confined. Labour was normal. Three weeks afterwards and without any preliminary symptom the old mental trouble returned. The same course of symptoms, mental and bodily, recurred. The duration of the illness was two months, at the end of which time the attack ceased and rapid recovery followed. Another—i.e., a sixth—pregnancy occurred. Six weeks after confinement the attack of insanity made its appearance, but on this occasion it lasted longer—viz., for four months. The mental disturbances were almost identical in evolution with those of the first two attacks, and the termination was also in rapid, almost abrupt, recovery. The other cases recorded display similar features of evolution of an attack as the above. "It is singular to note the comparative mental lucidity between the individual attacks," adds Dr. Gordon. All these cases showed a marked hereditary neurotic tendency. Dr. Gordon concludes that his observations confirm those of Krafft-Ebing and agree with recent cases published by Ziehen, namely that the periodic insanities are predominantly of hereditary origin and indicate a degenerative tendency in those subjects who manifest them.

SCHLATTER AND DOWIE.

"DR." DOWIE is in danger of turning even fanatics into sceptics. He should follow the best traditions of his kind in the United States and self-denyingly "go under." A timely disappearance has sometimes almost saved the reputation of a quack. This in some sort has been the case with a certain Francis Schlatter who as lately as 1895 enjoyed a huge reputation for thaumaturgy in Denver, Colorado. Schlatter had the appearance of an ascetic and probably did sincerely despise high living and riches. He seems to have remained poor and, wonderful to relate, disappeared at the very zenith of his fame. As lately as Sept. 17th, 1895, the *Rocky Mountain Daily News*, intoxicated as it were with the fame of the "Saint of Denver," published at the head of its columns a startling manifesto beginning with the words "Death to Doctors" and describing the merits of the prodigy of the south-west. Schlatter, the puff averred, cured rich and poor alike, provided only that they were halt, deaf, or blind. When patients could not reach Mr. Schlatter gloves were taken to them, which he had previously touched. The gloves were distributed twice daily—gratuitously, it would appear. Gloves rained in the house of a certain Mr. Fox, a "prominent citizen," who was thereby reported to be cured of the most obstinate form of deafness

---

[1] Lehrbuch der Psychiatrie, 1903.

He became Schlatter's ardent disciple and persuaded the master to become his guest. As if to expiate this acceptance of luxurious conditions Schlatter, one November night, quietly disappeared, leaving behind him this laconic scrap of blasphemy: "Mr. Fox, my mission is finished and the Father recalls me. I salute you; Francis Schlatter. Nov. 13th." He has not apparently been heard of since. Both Dowie and he are only links in a long chain of thaumaturgists whose prototype is lost in the mists of time "The mania for believing oneself inspired," Calmeil points out in his work "De la Folie," "for believing and announcing oneself a prophet, has been so frequently manifested among the sectaries of all religions, that we are embarrassed by the choice of examples of this deplorable unhealthy condition."

AN UNUSUAL APPLICATION.

A REMARKABLE instance of popular misconceptions with regard to the asylum treatment of insanity was supplied recently in the West of England. During an interval in the business of the Cornwall quarter sessions held at Bodmin on Oct. 21st the whole of a jury which had been engaged in the trial of a prisoner expressed a wish to visit the county asylum and for this purpose asked written permission from the chairman (Mr. W. C. Pendarves). The motives which prompted the jurymen to make this request were, no doubt, harmless enough; the strange feature of the case was their failure to understand that the coming and going of casual visitors would be singularly out of place in such an institution Unhappily, the majority of the patients suffer from chronic mental disorder, often associated with structural changes in the cerebral tissue, but when the symptoms have not been of long duration many regain their faculties and resume the positions which they held before their illness. This proportion of recoveries being an important justification of our elaborate and costly asylum system, the object of the medical superintendents is to make their institutions as far as possible hospitals for mental disease. In addition to being afflicted with one of the most terrible of maladies many of the patients are abnormally sensitive and anything which might suggest that they were being made subjects of exhibition would be intensely cruel. It is, however, only within a comparatively recent period that the public responsibility for the humane treatment of lunatics has been generally recognised. Even in 1844 the Commissioners in Lunacy in their reports to the Lord Chancellor complained of the prevalence of abuses and of the remissness of justices of the peace in attending to their duty of inspecting lunatic asylums, while in the eighteenth century Bethlehem Asylum in London was an everyday resort of idlers who paid a small admission fee for the purpose of being entertained by the antics and foolish talk of the inmates. Edward Ward, a well-known writer who died in 1731, introduces a visit to this asylum in his "London Spy" and has left a deplorable account of the scenes which were to be witnessed.

THE UNIVERSITY OF TORONTO AND ITS MEDICAL SCHOOL.

AT the annual convocation of the University of Toronto which took place on Oct. 2nd the honorary degree of LL.D. was conferred upon Professor William Osler of Johns Hopkins University, Professor C. S. Sherrington of the University of Liverpool, Professor Welch of Johns Hopkins University, Professor Keen of Jefferson Medical College, and Professor Chittenden of Yale University. The degree was also conferred *in absentiâ* on Professor Bowditch of Harvard University. The inaugural address, which was delivered by Professor Sherrington at the opening of the new medical and science buildings of the University of Toronto, will appear in our columns next week. The new buildings in question are chiefly intended for the study of physiology, pathology, and hygiene and are stated to be as fine as, or even finer than, any which we have in this country. The opening of these buildings was also marked by the union of the old Anglican School of Medicine—viz, Trinity College—with the University School, so that now the University School contains over 600 medical students and is the largest in Canada.

BETHLEHEM HOSPITAL.

WE have received a leaflet giving notice of a service of commemoration which was held in the chapel of the above hospital on Oct. 23rd. The order of service was a hymn, Evening Prayer up to the end of the Third Collect, the 130th Psalm, and another hymn. Then followed the address, two anthems, and the final hymn. The leaflet contains some interesting historical notes dealing with various important dates in the history of the hospital which was founded in 1247 as a Priory of St. Mary of Bethlehem; the following were the word of the Founder in his charter of foundation:—

> By reason of my reverence for my Lord and for His most tender Mother, to the honour and glory also of our Lord the King, to the benefit in manifold ways of the City of London, in which I was born, as well as for the salvation of my own soul, and for the salvation of the souls of my parents and friends, I have given to God and to the Church of St. Mary of Bethlehem all my land in the parish of St. Botolph, without Bishopsgate, with houses, gardens, orchards, ditches, and marshes, for the foundation of a Priory there, with a prior, canons, brothers, and sisters, who shall wear upon their mantles the badge of a star. And there shall be celebrated in the church to be erected there divine services for the souls aforesaid and for the souls of all the faithful dead And I have handed over the possession of all things aforesaid to Godfrey, Bishop of Bethlehem, to whom the said place shall pay one mark each year at Easter.
>
> This Charter of my Foundation I have signed and sealed on the Wednesday after the Feast of St. Luke, A.D. 1247. Witnesses:—Peter Fitz Alwyn, Mayor of London; Nicholas Bat, Sheriff; Ralph Sperlynges, Alderman; Godfrey de Campes, Simon the Tiler, Simon the Loriner, and others.

We are glad to see that the commemoration service has not been altogether dropped, though no doubt the intention of the founder was to include a *missa pro defunctis* We think it would not be out of the way to remind the authorities of the hospital that both before and after the Reformation there existed a number of services called dirges and one of these closely following the English use authorised in 1545 was sung last year in St. Paul's Cathedral on the burial day of the late Archbishop of Canterbury.

OBLITERATION OF THE SUPERIOR VENA CAVA.

IN the *Bulletin of the Johns Hopkins Hospital* for July Professor Osler has published an important paper on the rare condition of Obliteration of the Superior Vena Cava. While compression of this vessel is not very uncommon in cases of aortic aneurysm and mediastinal tumours complete obliteration with establishment of a collateral circulation is extremely rare. Only 29 published cases could be collected from literature. They can be classified as follows:—1. Thrombosis due to disease within the vein (10 cases). 2. Disease outside the vein (19 cases)—tuberculosis (four cases), mediastinitis (four cases), aneurysm (four cases), syphilis (three cases), periaortitis (two cases), carcinoma (one case), and fibroma (one case). The symptoms depend on the degree to which the collateral circulation is established. Any one of the three great veins of the body may be obliterated for years and the patient retain good health if the collateral circulation is complete. Professor Osler records the two following cases. A man, aged 23 years, was admitted to hospital complaining of dyspnœa, tightness of the chest, and swelling of the neck. Six weeks previously he went to bed feeling well and awoke with dyspnœa. He found that his neck was swollen and felt as though something was pressing on his chest. On admission the face and eyelids were puffy. The neck was full and pulsated and its veins were distended with blood. The superficial veins of the thorax and right upper arm were dilated. On Dec. 21st he was discharged improved. In December, 1899, he was re-admitted complaining of pain in the chest and swelling of the face. The thoracic subcutaneous veins anastomosed with the superficial and deep epigastric veins. The current in the thoracic veins was from above downwards. Radiography revealed nothing abnormal. In June, 1900, there were signs of pulmonary tuberculosis and the veins were more dilated. In February, 1901, he had a severe attack of dyspnœa with cyanosis and died. At the necropsy the innominate veins and upper part of the superior vena cava were found to have been converted into a fibrous mass. This was adherent to the spine which at this point was carious. There were many tubercles in the lungs. The left jugular vein was occluded; blood from the head must have passed mainly by way of the right jugular vein, through the right subclavian, pre-pectoral anastomosis with the anterior perforating branches of the internal mammary and with the subcutaneous tortuous veins, and superficial epigastrics to the inferior cava. An alternate course was from the subclavian to the upper right intercostal veins through the perforating branches of the latter and thence to the vena azygos which was very large. In the second case the patient was a man, aged 31 years, who was admitted to hospital in October, 1899, complaining of swelling of the neck and face. In 1884 he noticed that the right cervical glands were enlarged; afterwards the left ones were affected. In 1887 the enlargement much increased and about Christmas of that year the face was much swollen and the veins of the face, arms, and chest began to dilate. When he came under observation the face was suffused and swollen and the tongue was somewhat cyanosed. The venules were prominent and the veins of the cheeks and forehead were distinct. There was great enlargement of the cervical glands, particularly on the right side. The thoracic and abdominal veins were enormously distended. In September, 1890, the venous distension was still greater and in some of the veins over the manubrium thrombi could be felt. Death took place in March, 1893. The necropsy showed that the superior vena cava was obliterated by enlarged mediastinal glands.

THE DEATH-RATE FROM ALCOHOLISM.

THE difficulty of reconciling public and private interests is rarely more marked than in those cases where, in deference to the susceptibilities of patients and their friends, medical practitioners have to conceal information obtained by them in the course of their professional work which might be of great service to the community at large. How much, for instance, might be done to check the ravages of venereal diseases if popular prejudice would permit of their notification. Similarly, in cases of alcoholism the part played by the poison in causing death is usually obscured by the unwillingness of the attending physician to add to the troubles of sorrowing relatives by an outspoken declaration of the real state of affairs. Death certificates are consequently often much less instructive than they might be and the value of the statistics compiled for the Registrar-General is materially diminished through the application of the principle *de mortuis nil nisi bonum.* In Denmark and Switzerland an attempt is made to meet this objection by provisions which enable the medical man to give such details of an illness as considerations of public hygiene render desirable, while at the same time secrecy is preserved in regard to the failings of the particular individual. The arrangements in force in the latter country were described by M. Mahaim of the University of Lausanne at a recent congress held in Brussels. During the past 15 years in the case of 15 of the larger towns of Switzerland and during two years throughout that country it has been the custom for the certificate of death to be written on a card bearing merely a number instead of the name of, and other particulars about, the deceased, as with us. The identity of the person to whom the certificate refers can, however, be ascertained, if this becomes necessary, by a circuitous method which involves application to the central administration at Berne. In this way the practitioner is enabled to express in full his views of the nature of the illness without appearing unduly censorious. The value of such a removal of the restriction imposed upon the medical attendant by the requirements of professional propriety is shown by the figures relating to the effects of alcohol which have thereby become available. Switzerland is not, as far as we are aware, a country where alcoholic intemperance is peculiarly rife, yet it appears that the deaths from delirium tremens in males over 20 years of age amount to 0·5 per cent., which is ten times the rate in France as officially recorded. For males over 70 years of age alcohol is given as a principal or concomitant cause of death in 10 per cent. of the cases, while the general death-rate directly referable to acute or chronic alcoholism, without including hepatic cirrhosis or other subsidiary conditions, is 3 per cent. By the introduction into this country of some such method as is here described medical men would be given the opportunity of exercising a similar candour to that which characterises their brethren in Switzerland, and though the result would probably be rather distressing to our national self-esteem it could hardly fail to inculcate sundry valuable lessons.

PUBLIC VACCINATORS AND BOARDS OF GUARDIANS.

AT a meeting of the Chard board of guardians held on Oct. 19th a return of the cost of vaccination in the Chard union for four years prior to, and subsequent to the passing of, the recent Vaccination Act was read. We need not give the detailed figures but we may say that in general, though not in all districts, the number of vaccinations performed after the Act was passed had increased and in all the districts the expenses had gone up. Mr. Dening, the mayor of Chard, said that it was no wonder that the medical men were starting their carriages and pairs. Mr. Gawler asked if the demands were in excess of the regulated charges or if the medical men made their own charges, to which the clerk replied that the charges were strictly legal. Mr. Gawler thereupon said, "Then you cannot blame the doctors." In the *Chard and Ilminster News* of Oct. 24th a letter from Mr. Napier Close, public vaccinator for Chard borough, is published, which puts very plainly the case for a public vaccinator in a rural district. Mr. Close's district comprises an area of 7051 acres and the average sum received by him per annum for vaccinating throughout this district has been £39. Deducting estimated expenses, including materials for dressings, postage of notifications and the like, he actually receives each year £20 2*s.* 3*d.*, which works out at 1*s.* 3*d.* for each visit. He pointedly asks the editor of the *Chard and Ilminster News* to tell him of any member of any learned profession who would do such work for a like wage. Another letter appears in the same issue of the paper from Mr. Benjamin L. Powne, medical officer to No 1 Chard District, stating that at a meeting of the guardians held on Oct. 12th the chairman made "a perfectly one-sided statement." Mr. Powne also shows very clearly, while allowing that the expense to the ratepayers has increased, that the work of a public vaccinator has trebled. We may remark that an editorial paragraph in the same number of the *Chard and Ilminster News* which published the account of the board of guardians' meeting said: "Where are the anti-vaccinators? Now is their chance." In the same paper for Oct. 24th, after the publication of Mr. Close's and Mr. Powne's letters, another editorial paragraph stated that it should be well known that the new Act thrusts upon the public vaccinators an immense amount of work and responsibility, and that though the extra cost to the ratepayers has enormously increased it cannot be said that the price paid is too high, seeing that efficiency and thoroughness had been secured. Also that anti-vaccinationists are fortunately rapidly becoming extinct. We need not here labour the point that vaccination is a prophylactic against small-pox and we would point out to the Chard and Ilminster guardians that the charges made by medical men are perfectly legal, for according to the Vaccination Act of 1898 either the guardians agreed with the medical men to give them the fees which they received or else the charges have been fixed by the Local Government Board. It must be remembered that a vaccination does not simply consist in scratching a child's arm with a lymph-covered lancet but it may entail a long journey and always entails two or three inspections, careful dressings, the filling up of some six official documents, and a great deal of responsibility.

THE USE OF GLYCERINE INSIDE THE UTERUS.

IN a paper entitled "An Adjunct to Uterine Irrigation" which is published at p. 1229 of our present issue Dr. David Watson recommends the use of an intra-uterine injection of an ounce of glycerine containing 3 per cent. of formalin in cases of septic infection occurring after delivery. The question of intra-uterine irrigation in such cases is one upon which very varying opinions are held by different obstetricians. Most writers on the subject are agreed that in cases of pure streptococcic infection the use of such injections is best avoided. It has been shown that by the time the initial chill and rigor occur the organism has already invaded the tissues of the uterine wall and is beyond the reach of any antiseptic solution however powerful. In cases of mixed infections, and especially where the discharges are offensive, the employment of large quantities of, say, normal saline solution is valuable from its mechanical action in washing out the cavity of the uterus. The use of powerful antiseptics for this purpose is not only dangerous from the risk of poisoning but is actually harmful from the destruction of the already damaged tissues which they produce. Dr. Watson believes that watery solutions also act injuriously because they increase the amount of moisture in the interior of the uterus. To overcome this drawback he recommends for this purpose the solution of formalin in glycerine mentioned above. It must be remembered, however, that the introduction of glycerine into the interior of the uterus is not unattended with a special danger of its own. In 1890 Pelzer of Cologne advocated the method of inducing premature labour by injecting a small quantity of glycerine between the membranes and the uterine wall. A considerable number of cases was soon recorded, but it was not long before this method was found to be attended with much danger. Pfannenstiel showed that intra-uterine injections of glycerine were not uncommonly followed by the occurrence of hæmoglobinuria and in some cases by the death of the patient. Similar untoward results have occasionally attended the use of injections of iodoform and glycerine into the joints in cases of tuberculous disease. Such accidents are especially likely to follow when the patients are suffering from any renal affection and in these circumstances the intra-uterine injection of glycerine is strongly contra-indicated. In the case of a healthy woman recorded by Ferrari the intra-uterine injection of as small an amount as ten cubic centimetres of glycerine with every antiseptic precaution was followed in ten minutes by a rigor. Vomiting, hæmaturia, and diarrhœa set in almost immediately and the patient died from syncope two hours after delivery. At the post-mortem examination acute parenchymatous nephritis was found to be present. On account of the danger of such an occurrence this method of inducing labour has fallen into disrepute, and we should be afraid lest the more general adoption of the novel treatment suggested by Dr. Watson for cases of uterine sepsis might lead to equally disastrous results. That no such ill effects need be anticipated when glycerine is given in moderate doses by the mouth is shown by the experiences of Hermann. He has used the drug in 119 cases of nephrolithiasis in doses of from one to four ounces and has seen no bad results from its administration. The hæmoglobinuria that may follow the intra-uterine injection of the drug is no doubt to be explained by its immediate absorption by the blood-vessels and its direct action upon the blood. In this connexion it is interesting to recall the fact that the intra-vascular injection of glycerine is the method commonly employed in the physiological laboratory for producing experimental hæmoglobinuria.

THE WORSHIPFUL COMPANY OF PLUMBERS AND TECHNICAL EDUCATION.

THE Worshipful Company of Plumbers, whose persistent endeavours to raise the plumber to a level consistent with his responsibilities in relation to public health are well known, has recently published the first twelve of a series of full-size diagrams of plumbers' work. These diagrams have been prepared by a committee of practical men connected with the Plumbers' Company and illustrate the most approved modern practice of the trade. They are intended for the use of instructors in technical schools to supersede the usual rough black-board sketches and will tend to unify the existing methods of instruction. The first sheets are devoted to the illustration of some of the important scientific principles underlying the operations of the plumber. The drawings and appliances have an advantage over those frequently met with in that they illustrate general principles rather than the individual productions of certain manufacturers. The company has also reproduced the series in shilling pamphlet form with short descriptive notes, the value of which would have been increased had the notes been more extended. The pamphlet, however, is likely to be of use to architects, medical men, and others interested in the subject. The diagrams and pamphlet are published by the Plumbers' Company, at their office, 1, Adelaide-buildings, London Bridge, E.C.

THE PREVENTION OF TUBERCULOSIS IN IRELAND.

IN view of the continued high death-rate in Ireland from pulmonary tuberculosis the Local Government Board for that country has rightly deemed it desirable to re-issue the circular letter of Sept. 16th, 1901, to the district councils. This document set forth some of the resolutions of the International Congress on Tuberculosis which was held in London in that year and also impressed on the local authorities the importance of educating the people in the best means of guarding against the disease. In another letter dated Oct 6th of this year statistics are given showing the high death-rate from pulmonary tuberculosis which still exists in Ireland. The number of deaths from that disease in 1901 was 9549, representing a death-rate of 21·5 per 10,000 of the population. In England and Wales in the year 1871 the death-rate from this disease was 23 4 per 10,000, while in the year 1901 the rate of mortality had been reduced to 12·6. Such a marked difference in the figures for the two countries, as the Board points out, shows the necessity of taking prompt and sustained action with the view of reducing the present excessive mortality from pulmonary tuberculosis in Ireland. The fact that so considerable a reduction has been effected in England and Wales between the years above mentioned should act as an incentive to the local authorities of Ireland to use their best efforts towards securing a similar reduction in their country. We have always maintained that one of the most important forces in the combating of pulmonary tuberculosis is the education of the people and we entirely endorse the action which the Local Government Board has taken in again calling the attention of the local authorities to the matter. It has issued placards and leaflets clearly indicating the steps which should be adopted by "consumptive people and those who live with them" in order to prevent the spread of the disease. The information given is succinct and precise, it is stated in terms that can easily be understood by everybody, and with the aid of medical practitioners could be made to yield results which would show themselves by a considerable reduction in the deathrate from pulmonary tuberculosis.

PATHOLOGICAL SPECIMENS AT ST. GEORGE'S HOSPITAL.

THE practice of showing at the beginning of each winter session all the specimens that have been added to the pathological museum during the past year has been in force for some years now at St. George's Hospital and the exhibitions this year contain some particularly interesting objects. A short type-written description of each specimen with brief references to the case of the patient from whom it comes is appended in each instance. Those interested in any particular specimen can thus easily obtain fuller particulars of the clinical history of the individual from whom it is taken. The mounting and descriptions of the specimens reflect great credit upon the industry of the curators and the students at St. George's Hospital may congratulate themselves upon the support that they can easily obtain from such exhibitions as this to supplement and to enliven their clinical observations. A cysticercus in the brain, an embolism of the splenic artery, and some remarkable growths and abnormalities of the abdominal organs are among the specimens most worthy of attention. The hospital authorities welcome any medical man who cares to inspect the exhibition which is in the museum of the medical school.

IMPROVEMENT SCHEME IN JOHANNESBURG.

ON the British occupation of Johannesburg in June, 1900, Major O'Meara, the acting burgomaster, formed the opinion that a considerable area within the limits of the town was in an insanitary condition and would be a source of exceptional danger if bubonic plague, which was then raging at Cape Town, should make its way to Johannesburg. Lord Milner therefore in September, 1902, appointed a commission consisting of five members to report as to the condition of the area and also as to the desirability of giving powers to the town council to expropriate any of the land or buildings thereon. The area consisted of about 172 acres held by some 700 owners and having a total population of about 5600 persons. The procedure adopted was that the town council should adduce evidence as to the insanitary state of the area and that owners, lessees, and occupiers should hand in objections and call evidence in support of them. On behalf of the objectors five witnesses were called and on behalf of the town council 20 were called, including Dr. Charles Porter, medical officer of health of Johannesburg. In their report the commissioners state that they were much impressed by Dr. Porter's knowledge of the questions to be considered and also by the admirable way in which his evidence was presented. The commission took the view that the area was insanitary and dangerous to public health and that expropriation was advisable.

THE SWINEY PRIZE.

THE council of the Society of Arts has recently decided that the twelfth quinquennial award of the Swiney prize for work in some branch of jurisprudence shall be made in January, 1904. Intending competitors for this prize, which consists of a sum of £100, together with a cup of the same value, will have their claims investigated by the Society of Arts and the Royal College of Physicians of London conjointly. Medical jurists have on several occasions been successful, the list of gentlemen so honoured containing the names of Dr. J. A. Paris, Dr. J. Fonblanque, Dr. A. Swaine Taylor, Dr. W. A. Guy, Dr. Norman Chevers, Dr. C. M. Tidy, and Dr. J. D. Mann. In accordance with precedent, since the last award was made for research in forensic medicine the next recipient will probably be sought for in some other field of legal activity, but it is open to any medical man to submit evidence of his title to consideration. Applications should be made to the Secretary of the Society of Arts, John-street, Adelphi.

VACCINATION EXPENSES.

THE departmental committee appointed by the President of the Local Government Board to inquire into, and to report with regard to, the payments made to public vaccinators and vaccination officers under the Vaccination Order, 1898, on Oct 21st heard the evidence of Mr. C. A. Kemble, chairman of the board of guardians of the Clutton Union; Mr. J. T. Beston, a member of the Birmingham board of guardians; and Dr. H. W. Langley Browne, public vaccinator of the West Bromwich Union. On the 22nd Dr. A. E. Cope, Dr. A. Drury, and Mr. A. Maude gave evidence on behalf of the Association of Public Vaccinators of England and Wales. We understand that the committee is now proceeding to consider the evidence given with a view to drawing up its report.

THE Hughlings Jackson Lecture of the Neurological Society of the United Kingdom will be delivered by Sir William Broadbent, Bart, M.D., F.R.S., K.C.V.O., at 11, Chandos-street, Cavendish-square, on Thursday, Nov. 5th, at 9 P.M. The subject will be "Hughlings Jackson as Pioneer in Nervous Physiology and Pathology."

Sir William Taylor, K.C.B., Director-General of the Army Medical Service, will preside at a dinner of the Glasgow University Club, London, to be held on Thursday, Nov. 26th, in the Trocadéro Restaurant. Particulars may be obtained from Mr. James Dodds, Dover House, Whitehall, or from Dr. C. O. Hawthorne, 28, Weymouth-street, W.

THE Harveian Lectures of the Harveian Society will be delivered this year on Nov. 5th, 12th, and 19th by Dr. D. B. Lees, at the Stafford Rooms, Titchborne-street, Edgware-road, London, W. The subject selected by Dr. Lees for his lectures is the Treatment of Some Acute Visceral Inflammations.

IN the Cape Colony for the week ending Oct. 3rd there were two cases of plague discovered—namely, one European male and one native male, both at Port Elizabeth. Plague-infected rats were found at East London.

THE meeting of the Pathological Society of London announced for Tuesday, Nov. 3rd, will not be held.

THE ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.

Annual Meeting

THE annual meeting of the above association was held on Friday afternoon, Oct 23rd, at the Hotel Cecil the President, Mr E **Climson Greenwood**, occupying the chair The reports of the council and of the organising secretary, which had been placed before the members, showed that as a result of various representations the President of the Local Government Board had instituted an inquiry, which was then being held at Whitehall, as to the payments to public vaccinators and vaccination officers Evidence was being tendered on behalf of the association by three of its members It was gratifying to observe from this that the association had been officially recognised as a representative association Another encouraging feature was the liberal response of the members to the appeal for a special guarantee fund The most important part of the work of the association during the year however, had been in the direction of organisation, the establishment of 14 district councils representing all the public vaccinators in various districts of England and Wales indicating the amount of success achieved There still remained a good deal to be done in that direction as it was estimated that 27 more councils were required to cover completely the ground

The report and balance sheet having been passed, the election of president took place, the result being that Mr Greenwood was unanimously re-elected for the ensuing year The election of the council produced three changes in its *personnel* Dr Arthur Drury (Halifax), Dr S Woodcock (Manchester) and Mr G W Brabyn (Wimbledon) taking the places of Dr Mahomed Dr O P Oliver, and Dr Thompson

Dr A E **Cope** referred to the immense amount of work the organising secretary had accomplished during the past year and said that to his indefatigable exertions was mainly due the success of the association

The **Organising Secretary** briefly dwelt on the progress the association had made during the year, referring particularly to the establishment of the district councils which it was expected would be of immense service to them Since the issue of the report four more councils had been established, bringing the number up to 18 and three others would be shortly added to the number so that they hoped gradually to cover the whole of England and Wales

Dr **Cope** then read a very able and exhaustive paper on Our National System of Vaccination—How can it be improved? He thought that the one all important factor in any really national system of vaccination should be the absolute equality and uniformity of administration in every part of the country and that could only be obtained by centralising the system There was one branch of the public service which was completely organised and uniformly administered and free from all local political influence—that was the registration service That system was ready to hand as a framework on which to expand and to develop a national system of vaccination Vaccination should he held be approximated to registration in its organisation and method and gradually withdrawn from its Poor law associations While Poor law administration was still a local administration vaccination should be considered as a national administration the same as registration The new organisation could be built upon the existing substructure There would be 11 divisions as at present for registration purposes, which would be subdivided into counties and districts and each division would have a superintendent public vaccinator and a superintendent vaccination officer He believed that an extension of vaccination organisation in the direction indicated accompanied by fixity of tenure would greatly improve the system and make it truly national After touching upon the question of how vaccination should be paid for, Dr Cope went on to deal with the payment of the public vaccinator himself It would be desirable that in metropolitan and large urban districts at all events, the public vaccinator should be either a whole time man or should not engage in practice which would put him in competition with the medical men in his district. He thought that all opposition would be disarmed and the public vaccinator would be able to render more efficient service if that were the case He need not be restricted entirely to vaccination in all cases He (Dr Cope) could not see why the public vaccinator should not be allowed to take appointments which would not interfere with his vaccination work, such as district medical officer, or why he should not be permitted to engage in special or consulting practice provided he obtained the sanction of the Local Government Board or the controlling authority This vaccination appointment should be permanent and carry with it superannuation Dr Cope also dealt with the necessity for a system of revaccination after the manner obtaining in Germany and he strongly urged that something should be done towards educating the public on vaccination matters

An interesting and animated discussion followed in which a number of members took part

Mr A **Maude** complimented Dr Cope on his admirable paper and said he agreed mainly with the views expressed. They could not expect such an efficient system of registration in this country as obtained in continental countries but they should make the best use they could of the available machinery, and if they connected vaccination with State registration he considered it would be best all round He strongly favoured the adoption of a system of revaccination approaching as near as possible to the German system

Dr G A **Miskin** suggested that as so many children escaped vaccination through the parents moving it should be compulsory for changes of address to be notified to the registrar or vaccination officer

Dr W **Gosse** hoped that the new Act would make it very clear that the onus of having the child vaccinated should be on the parents If the parents failed to carry out the law they should be punished He saw objections to rural districts being covered entirely by a man who did nothing else

Mr W **Holder** differed considerably from Dr Cope on the question of a public vaccinator not being allowed to engage in medical practice They as public vaccinators had been doing their work efficiently and he could see no reason why the Government should wish to make a change and take the duties from those who had attended to them for so many years

Dr **Drury** said that Dr Cope had gone to the very fountain head as to the possible improvement, and perhaps the only thing for improvement under the present Act, which was simply the administration of it He believed that every man in the room was prepared to say that the Act was a very good one As to the question of the whole-time man, there were many things to be said in favour of it but only in large congested areas It would not be practicable in rural districts But Dr Cope himself suggested an argument against it where he insisted on the desirability for uniformity and any interference with the uniformity of the vaccination service would cripple it He noticed during the last five or six years that the tendency was when vacancies occurred for the guardians to cut up the districts rather than to enlarge them

Mr W N **Clemmey** referred to the conscientious objector clause and mentioned that the Act of Parliament said that the magistrate must be satisfied but if they got two magistrates on the bench one being satisfied and the other not, what was to be done? He thought the form should read that any parent who came before the magistrate and produced two certificates, one signed by a medical practitioner and the other signed by the public vaccinator of the district, to say that vaccination would be injurious to the child, the magistrate should grant the certificate of exemption which should be in force till the child reached the age of five years.

Mr V A ***Jaynes*** *said that the first object of the association* was to improve the position of the public vaccinator. What they wanted he considered, was to be under the Local Government Board and to have fixity of tenure

Other members spoke and Dr **Cope** in his reply, wished it to be understood that what he had written in his paper was absolutely irresponsible so far as the association was concerned In regard to his remarks about the whole-time public vaccinator or the man who was restricted with regard to private practice that had a very limited application There were half a dozen men in London who were occupying that position at present. He distinctly limited it to the metropolis and large urban districts but might possibly have given a wrong impression in his paper He would never lift a finger to enlarge a public vaccinator's district at the expense of any other public vaccinator nor would he prevent a public vaccinator taking an adjacent appointment if it were vacant. Dr. Miskin's suggestion about reporting removals he thought would be unworkable. No penalty which they could impose would insure the due registration of changes of address. He agreed that the parents of a child who had reached the age of five years should be required to produce evidence of the latter having been vaccinated.

A hearty vote of thanks was accorded to Dr. Cope for his valuable paper.

MEDICINE AND THE LAW.

Faith-healing and Cruelty to Children.

AT the recent quarter sessions at Ipswich a tailor named Sach was tried for neglecting his adopted child, a little girl five years old, in a manner likely to cause her unnecessary suffering. It was proved that the child was knocked down by a cart and that her thigh was thereby fractured. Prayer was resorted to as a remedy and an evangelist of the "Christian Catholic Church in Zion" told an officer of the National Society for the Prevention of Cruelty to Children a few days later that the "symptoms were lovely." The adoptive father and mother in the witness-box declared their belief in the efficacy of prayer in these circumstances with such effect that the punishment imposed upon them was limited to a fine of £20. With all respect for the faith which leads persons of this class to endure a modified martyrdom for the sake of their principles it may be suggested that steps should be taken for the protection of helpless little children in such families. If power were to be given by law to remove the children from their parents, at all events after a first conviction, the parents might be compelled to contribute towards their maintenance without being permitted to let them suffer or die without aid when sick or injured. Within a few days of the trial of Sach a coroner's jury at Leeds recommended that another member of the "Christian Catholic Church in Zion" should be censured for allowing her daughter, aged 17 years, to die. In this case the mother does not appear to have had enough faith in prayer to invoke the aid of the elders of her church. She merely said that she "had no faith in a doctor's medicine" and left her child to die without medical aid.

Recent Cases of Cruelty.

Two trials which have taken place in different parts of the country during the recent county quarter sessions have attracted universal attention. In the one a young solicitor named Edalji was convicted and sentenced to seven years' penal servitude at Stafford for maiming cattle and horses in the neighbourhood of Great Wyrley. In the other a woman named Day was at Exeter convicted and sentenced to six months' imprisonment with hard labour for repeated acts of cruelty perpetrated upon one of her children. The principal facts of these two cases are well known and need not be recapitulated. They present features frequently observable in cases of apparently aimless cruelty and some of these are common to both of them. In neither could the prosecution suggest any motive for the acts done. Edalji had no proveable grudge against the farmers whose animals he mutilated. For this reason his acts are clearly to be placed in a totally different category from that of a man who was convicted in London on the same day for maliciously killing a mare. In that case the prisoner was employed by the owner of the animal, which he stabbed in the belly with a pitchfork immediately after receiving notice to quit his mistress's service, being actuated beyond doubt by anger and revenge. At the trial of Mrs. Day no reason was proved to account for her dislike for the children whom she ill-treated (for there was a second indictment against her referring to a second child which was not gone into) and it was not alleged that towards the rest of her family she was anything but a humane mother. In her case the marked antipathy towards one or two of her children is a feature which was observable in that of Mrs. Penruddocke, a lady whose acts were less cruel and were very much more lightly punished than hers. In the case of Edalji and in that of Mrs Day, moreover, no possible motive, had one existed, would have justified, or even palliated, that which was proved to have taken place. Resentment, for example, for wrong done to him could not have excused Edalji, nor could the necessity for disciplinary action have rendered permissible the monstrous indignities and tortures inflicted by Mrs. Day upon a child of tender years. Whereas, however, acts of cruelty committed without any apparent object beyond the infliction and contemplation of suffering are strongly suggestive of some degree of mental alienation upon the part of the person charged with them, the trials of Edalji and of Mrs. Day presented another common feature which precluded the possibility of any inquiry into the mental condition of either of them. In each case the defence was based upon a denial of guilt. Both prisoners were defended by solicitors and by counsel of experience briefed on their behalf. Both prisoners went into the witness-box to deny the acts alleged against them and to have their denials tested by cross-examination, and in the case of both of them relatives or friends were ready to come forward to support them in their defence. In such circumstances there was obviously no room for any suggestion at the two trials in question of any peculiarity of mind or temperament which might account for the deeds the perpetration of which was denied. Edalji and Day as a result take their places under the sentences passed upon them in the ranks of ordinary prisoners. Possibly their mental condition may be made the subject of special observation when in prison and they may be treated according to the result. It is hardly desirable that a man with the propensities which apparently influence Edalji should resume unrestricted liberty, and it is to be hoped that the National Society for the Prevention of Cruelty to Children will not altogether lose sight of Mrs. Day when her family, Joan excepted, is restored to her.

The Medical Evidence in the Case of Mrs. Day.

At the trial of Mrs. Day at Exeter referred to in the preceding paragraph, as at that of Mrs. Penruddocke at the Old Bailey for a similar offence, the most important evidence corroborating the story of the child as to her treatment was that of a medical witness. Dr. W. A. Valentine of Appledore, called on behalf of the prosecution, said that he had examined the child Joan Day on two occasions, the first being August 4th, a week before her removal from her mother. She then appeared to be frightened. He found marks upon her hands and arms consistent with her story that her mother had cut her arms, had scratched her hands, and had bitten one of her fingers, also marks consistent with her story that her hand had been burnt by her mother. There were 12 marks on her right hand and arm and 11 on the left, a condition which in itself could hardly be accounted for by the explanation of the defence that she was a clumsy child and given to hurting herself accidentally. Counsel for the prosecution laid considerable stress upon the evidence of Dr. Valentine in summing up to the jury, and so did Lord Coleridge, K.C., the chairman of the bench. The former also called attention to a significant fact. He pointed out that a second medical man had twice examined the two children with regard to whom charges of cruelty were made and had done so avowedly in the interests of Mrs. Day. If his opinion had not agreed with that of Dr. Valentine he could have come to the court to say so and from the fact that he was not called by the defence counsel invited the jury to draw the conclusion, which indeed seems irresistible, that their views coincided. Two other medical men besides Dr. Valentine gave evidence in the course of the trial, one of whom, Dr. W. G. Dickinson of Putney Heath, called for the prosecution, proved that Joan Day's arm had been broken when her mother was living at Wandsworth. He stated frankly that so far as his observations went Mrs. Day was anxious about her children when they were ill. Mr. C. K. Ackland of Bideford, called for the defence, had attended Joan Day upon one occasion when she made no complaint of ill-treatment and upon another when she complained of feeling ill but he could find nothing the matter with her. He expressed an opinion that the marks stated by the child to be cuts could not have been inflicted as she said they had been, although they were also inconsistent with her little sister's story that they were the result of an accident, and he also commented upon the remarkable nature of the story told by John Day that she had been made to remain naked in the garden during the greater part of a frosty night and had apparently suffered no ill-effects from the alleged exposure. The evidence of Mr. Ackland no doubt affected the verdict of the jury who, in finding the prisoner guilty, recommended her to mercy on the ground that some of the acts alleged had not been proved to their satisfaction. That no complaint had been made by the child either to Dr. Dickinson or Mr. Ackland was in no way remarkable and it was not likely that Mrs. Day would exhibit her propensities before them. They were called in as medical men to attend her family and it was not for them to suspect her of inhumanity or to constitute themselves investigators of her relations with her children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8386 births and 4610 deaths were registered during the week ending Oct. 24th. The annual rate of mortality in these towns, which had been 15·3, 15·8, and 15·8 per 1000 in the three preceding weeks, further rose to 15·9 per 1000 last week. In London the death-rate was 15·1 per 1000, while it averaged 16·3 in the 75 other large towns. The lowest death-rates in these towns were 4·0 in Hornsey, 6·8 in Leyton, 7·1 in Burton-on-Trent, 7·4 in King's Norton and in Newport (Mon.), 9·0 in Willesden and in Wallasey, and 9·2 in Aston Manor; the highest rates were 21·8 in Merthyr Tydfil, 21·9 in Preston, 23·0 in Sunderland, 23 1 in Hanley, 24·1 in Middlesbrough, 24·2 in Salford, 24·6 in Rotherham, and 30·8 in Tynemouth. The 4610 deaths in these towns last week included 532 which were referred to the principal infectious diseases, against 697, 707, and 634 in the three preceding weeks; of these 532 deaths, 291 resulted from diarrhœa, 58 from diphtheria, 55 from measles, 46 from "fever" (principally enteric), 45 from whooping-cough, 36 from scarlet fever, and one from small-pox. No death from any of these diseases was registered last week in Hornsey, Ipswich, Burton-on-Trent, Bootle, or Newport (Mon.), while they caused the highest death-rates in West Bromwich, Birkenhead, Warrington, Burnley, Preston, Rotherham, Middlesbrough, Sunderland, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Warrington and Sunderland; from scarlet fever in West Bromwich; from diphtheria in Bournemouth; from whooping-cough in Birkenhead; from "fever" in Merthyr Tydfil; and from diarrhœa in West Ham, Birmingham, Aston Manor, Burnley, Preston, Rotherham, and Middlesbrough. One fatal case of small-pox was registered last week in Gateshead, but not one in any other of the 76 towns. The Metropolitan Asylums hospitals contained 34 small-pox cases on Saturday last, Oct. 24th, against 21, 17, and 11, on the three preceding Saturdays; 26 new cases were admitted during last week, against one, two, and one in the three preceding weeks. The number of scarlet fever patients remaining under treatment in these hospitals and in the London Fever Hospital, which had been 1876, 1881, and 1861 at the end of the three preceding weeks, had further declined to 1858 at the end of last week; 209 new cases were admitted during the week, against 235, 240, and 208 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 161, 146, and 175, in the three preceding weeks, further rose to 194 last week, but were 57 below the number in the corresponding period of last year. The causes of 58, or 1·3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Nottingham, Salford, Bradford, Leeds, and 46 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, St. Helens, Blackburn, Sheffield, South Shields, Gateshead, and Newport (Mon.).

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·3, 16·0, and 16·1 per 1000 in the three preceding weeks, further rose to 16·7 per 1000 during the week ending Oct. 24th, and was 0·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·8 in Leith, and 13·9 in Perth, to 19·5 in Paisley and 21·0 in Greenock. The 546 deaths in these towns included 39 which resulted from diarrhœa, 16 from measles, eight from whooping-cough, six from "fever," four from scarlet fever, and four from diphtheria, but not any from small-pox. In all, 77 deaths were referred to these principal infectious diseases last week, against 65, 71, and 72 in the three preceding weeks. These 77 deaths were equal to an annual rate of 2·4 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 42, 41, and 35 in the three preceding weeks, rose again last week to 39, of which 14 were registered in Glasgow, seven in Aberdeen, six in Dundee, four in Edinburgh, three in Paisley, two in Leith, and two in Greenock. The deaths from measles, which had been four, eight, and 14 in the three preceding weeks, further rose last week to 16, all of which occurred in Glasgow. The fatal cases of whooping-cough, which had been seven, six, and seven in the three preceding weeks, further increased to eight last week, and included four in Glasgow and two in Aberdeen. The deaths referred to different forms of "fever," which had been six, nine, and six in the three preceding weeks, were again six last week, and included two in Glasgow, two in Dundee, and two in Greenock. The fatal cases of scarlet fever, which had been two, four, and five in the three preceding weeks, declined again last week to four, of which two occurred in Edinburgh and two in Aberdeen. The four deaths from diphtheria corresponded with the number in the preceding week, and included two in Edinburgh and two in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 88, 62, and 82 in the three preceding weeks, further rose last week to 92, but were 24 below the number in the corresponding period of last year. The causes of 17, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·3, 19·7, and 18·6 per 1000 in the three preceding weeks, rose again to 21·5 per 1000 during the week ending Oct. 24th. During the past four weeks the death-rate has averaged 19 5 per 1000, the rates during the same period being 14·8 in London and 15·7 in Edinburgh. The 156 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 21 over the number in the preceding week and included 13 which were referred to the principal infectious diseases, against nine in each of the two preceding weeks; of these, eight resulted from diarrhœa, four from "fever," and one from whooping-cough, but not any from small-pox, measles, scarlet fever, or diphtheria. These 13 deaths were equal to an annual rate of 1 8 per 1000, the death-rates last week from the principal infectious diseases being 1·4 per 1000 both in London and in Edinburgh. The fatal cases of diarrhœa, which had been three, four, and five in the three preceding weeks, further rose last week to eight. The deaths referred to different forms of "fever," which had been one and three in the two preceding weeks, further rose to four last week. The 156 deaths in Dublin last week included 40 of children under one year of age and 40 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a considerable excess over the number recorded in the preceding week. Nine inquest cases and eight deaths from violence were registered, and 48, or nearly one-third, of the deaths occurred in public institutions. The causes of nine, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. R. McDonnell to the *Æolus*; T. J. Crowley to the *Albemarle*; and H X. Browne to the *Cambridge*. Staff Surgeons: J. K. Robinson to the *Donegal*; E. St M Nepean to the *Centurion*; J. O Wood to the *Arrogant*; J. L. Smith to the *Revenge*; and W. Bett to the *Bedford*. Surgeons: J. G. Peebles to the *Donegal*; S. S. H. Shannon to the *Centurion*; A. F. Fraser to the *Albemarle*; A. I. Sheldon to the *Hearty* for the *Landrail*; H. Hunt to the *Fire Queen*, additional; M. J. Laffan to the *Bedford*; and W. R. Harrison to the *Tweed*.

ROYAL ARMY MEDICAL CORPS.

Major G. W. F. Long, from half-pay, to be Major, with precedence next below B. A. Maturin (dated Oct. 6th, 1903). Major M. T. Yarr is seconded for service on the Staff of the Governor of Bombay (dated Oct. 9th, 1903).

IMPERIAL YEOMANRY.

Scottish Horse: David Mitchell Macdonald to be Surgeon-Lieutenant (dated Oct. 24th, 1903).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Surgeon-Lieutenant T. S. Allan resigns his commission (dated Oct. 24th, 1903). 2nd (the Weald of Kent) Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Lieutenant J. L. Kerr to be Surgeon-Captain (dated Oct. 17th, 1903).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Glasgow Companies: William Adam Burns to be Lieutenant (dated Oct. 17th, 1903).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

The Seaforth and Cameron: Lieutenant D. J. Kelly resigns his commission (dated Oct. 17th, 1903).

DEATHS IN THE SERVICES.

Surgeon-Lieutenant-Colonel Robert Vacy Ash, late Army Medical Staff, recently, at Morecambe, aged 58 years. He entered the service in 1871, was promoted surgeon in 1873, surgeon-major in 1883, and retired as surgeon-lieutenant-colonel in 1891 He served in the Zulu War of 1879 and in the operations against Sekukuni (medal). He served in the Egyptian War of 1882 and was present at the battle of Tel-el-Kebir (medal with clasp and the Khedive's star). He also took part with the Burmese Expedition in 1886–87 (mentioned in despatches, medal with clasp).

REGIMENTAL COTTAGE HOMES.

The Wiltshire Regiment intends to erect a cottage home near the barracks at Devizes as a permanent memorial to the seven officers and 127 men of the regiment who fell in South Africa. General Dunne, colonel of the regiment, and president of the regimental committee which has been formed, has issued an appeal for subscriptions to complete the required sum, any surplus being devoted by the regiment to the payment of rents of disabled soldiers.

Correspondence.

"Audi alteram partem."

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—At the monthly meeting of the British Medical Benevolent Fund held here this afternoon, 12 members being present, I was called upon by a unanimous vote to make an appeal on behalf of the fund. The circumstances are as follows. There were 19 applications for help from medical men, their widows or daughters, while at the opening of the meeting our treasurer, Dr. S. West, announced that there was a deficit of £52, the account having been overdrawn to this amount in consequence of the urgency of the cases brought before the committee in September. Notwithstanding this the committee proceeded to vote £39, making a total adverse balance of £91 in the hope that somehow or other the money would be got together rather than refuse the more distressed applicants the aid they need. The committee could not venture on more.

The following are examples of the distress the fund is called upon to relieve, and it must be borne in mind that it is the only professional charity open for the wreckage of the profession with the exception of THE LANCET Relief Fund which deals with acute rather than chronic cases.

Mr. ——, aged 57 years, M.R.C.S., L.S.A., suffers from varicose veins and ulcers which have prevented active practice for some years past; now only able to earn about £20 per annum.

Miss ——, aged 27 years, suffers from acute spinal disease and has not walked for eight years. *Only* means of support 5*s.* a week allowed by a friend.

Mr. ——, aged 50 years, M.R.C.S., L.R.C.P., who practised for many years in London; incapacitated by advanced valvular disease with dropsy and embolism; savings exhausted; three children partially dependent.

Mrs. ——, aged 49 years, a widow. Husband practised in the north of London, but made no provision for his wife who has supported herself for several years as an obstetric nurse. Now incapacitated by cataract in both eyes.

Mrs. ——, aged 41 years, a widow. Husband had an excellent practice in the Midlands but lost it through a five years' illness, leaving wife and four young children quite unprovided for.

Mr. ——, aged 45 years, who practised in South Africa. Savings exhausted by a three years' illness. The honorary local secretary reports that applicant is nearly starving and that his destitute condition is due to misfortune and not to any fault of his own.

Miss ——, aged 49 years, whose father practised in Staffordshire, has supported herself as governess for 30 years but health has now broken down.

The two last were on to-day's list. £5 were devoted to one and the other had to be postponed as, out of five new cases, four were not even considered owing to the impossibility of helping. Of the old cases some were postponed in the hope of having money available next month and to two or three quite small and inadequate grants were made. The annuity department of the fund has continued to prosper and has now a list of 115 rescued from actual destitution in their old age. Every really necessitous case over the age of 60 coming to the notice of the committee is entered as a candidate and as vacancies occur they are at once filled up from the list after careful inquiry. 27 are now waiting their turn and in 1902 15 were elected at ages varying from 90 to 60 years, amongst them a M.R.C.S. aged 74 years.

It is the donation department which is in need of help. Last year grants were made to 161 applicants, the amount voted being £1723, mostly paid in monthly instalments, since this method has been found greatly to enhance the benefit to the recipients. Times almost everywhere are bad and the profession is suffering from the general financial depression, but we must not let the unfortunate of our number suffer from cold and hunger during the winter months or look forward to Christmas and the New Year in actual privation. There are few more piteous cases than those of widows and daughters of medical men left unprovided for by the premature death or totally inadequate earnings of the husband or father. Many of those who are ultimately driven to seek the aid of the fund have maintained themselves for years till overtaken by old age or illness.

Donations may be sent to the honorary treasurer, Dr. West, 15, Wimpole-street, or I shall myself be happy to acknowledge them.

I am, Sirs, yours faithfully,
W. H. BROADBENT,
President of the Fund.
84, Brook-street, Oct. 20th, 1903.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—I think Dr. Harry Campbell in his letter to THE LANCET of Oct. 24th, p. 1191, makes a valuable contribution to the study of the lung reflex and while there are certain other facts not mentioned in my previous letter on this subject which go to establish beyond any doubt the existence of the reflex in question I may, perhaps, first be permitted to deal shortly with the thoughtful observations of Dr. Campbell.

The view is expressed that expansion of the chest in the living body is due to the operation of two factors—one, a relaxation of the lung, and the other, action on the part of the respiratory muscles. Assuming for the sake of argument that a lung reflex of dilatation is produced, the result would be an expansion of the chest wall due to diminution of suction action *plus* action of the inspiratory muscles. Now I am not sure that every degree of lung relaxation is accompanied by action on the part of the inspiratory muscles, because we know that at the end of an ordinary inspiration the chest wall has not even then reached its full recoil. This is proved by experiments on the dead body when, on puncturing the chest wall and so permitting the lungs to collapse, it is found that the thoracic wall registers an expansion somewhat greater than that registered within the limits of quiet respiration. There is a certain point, therefore, to which the chest wall may expand beyond an ordinary inspiration which does not necessitate any action on the part of the inspiratory muscles, as the inhibition of the lung pull is of itself sufficient to produce it. The contention of Dr. Campbell that "the inspiratory muscles are ever busy keeping the lungs at the requisite degree of stretch" may be doubtless true in the case of spasmodic asthma or in hypertrophous emphysema, where the pulmonary suction is abolished or nearly so, but in normal breathing, matters are precisely the reverse, as herein, instead of the inspiratory muscles acting to tone up the pulmonary fibres, their action is directed towards overcoming this tonus. It is only when a relaxation of lung occurs to such an extent as to pass the indifferent point that the inspiratory muscles are necessarily called into play in the direction of "toning up" the lung fibres. It was certainly the original view, as propounded by Hutchinson,[1] that the inspiratory muscles acted in the normal respiration not only in overcoming the elastic resistance of the lungs but also a resistance on *the part of the chest walls. But some time afterwards* Salter[2] made the important observation above referred to on the elastic recoil of the chest wall following post-mortem puncture of the pleura, and this resiliency was accurately estimated subsequently in a number of very careful experiments by Sir R. Douglas Powell.[3] When, therefore, Dr. Campbell makes the general assertion that "any enlargement of the chest ...... is chiefly brought about by the inspiratory muscles," he fails to appreciate that enlargement (up to a certain point) which is brought about by the reserve recoil of the chest walls.

As regards the lung reflex, once it be proved that bronchial (and therefore pulmonary) dilatation can be induced by stimuli applied to the chest wall or otherwise, it is a matter of secondary consequence how far the inspiratory muscles thereafter contribute to the thoracic enlargement, but Dr. Campbell goes so far as to assert that the entire phenomena of the lung reflex may in fact be due to reflex excitement of the inspiratory muscles themselves. Now, in regard to the chest generally, it is doubtless true that such a procedure as vigorous rubbing tends to induce, if not dyspnœa, at least a deeper character of the breathing. In neurotic persons this is sometimes very marked, but that this is chiefly the result of a reflex pulmonary relaxation is shown by examining the state of the lungs and comparing the same with the effect produced by simply getting the patient to draw a number of deep breaths. In the former case there is a distension of lung which persists for some time after the breathing has become quiet, whereas in the latter case the distension subsides with the breathing; in other words, the mean size of the chest is more persistently enlarged when the lung reflex is induced, and if the cutaneous stimulus be maintained for some time this expansion is correspondingly maintained. The conclusive evidence, however, as to the existence of the lung reflex of dilatation is that afforded by the application of stimuli over small areas of lung which have been invaded by collapse. If such a small area be irritated, as by spraying with ether, it will be found that the percussion note, formerly dull, will acquire some resonance, and I have observed that the same effect is frequently produced by prolonged *percussion over the area. Now such an effect* over a limited area, say at the base of the lung, is only susceptible of one explanation—viz., a reflex dilatation of the collapsed air cells. If the dilatation were produced by a dyspnœa involving the action of the inspiratory muscles the remaining portions of the lungs would likewise be dilated, whereas no dyspnœa is apparently produced nor are the lungs otherwise altered in volume.

As regards the reflex of dilatation which is induced by the inhalation of certain irritating vapours and which Dr. Campbell believes to be merely an effect of inspiration, it may be sufficient to point out that the reflex of dilatation can also be brought about by the oral administration or the subcutaneous injection of such drugs as atropine and hyoscine wherein inspiratory effort is wanting.

I am, Sirs, yours faithfully,

Henrietta street, W., Oct. 24th, 1903. A. G. AULD.

SLEEPING SICKNESS: A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I have just learnt that I have been credited with the statement, made in certain newspapers this week, that a Liverpool student discovered the cause of sleeping sickness. *I did not make any such statement*, nor have any of the members of our Liverpool school ever made such a statement. *We have not sent any expeditions from Liverpool to the* sleeping-sickness area with the exception of the expedition very recently sent to the Congo. I would be much obliged if you could give publicity to this statement.

I am, Sirs, yours faithfully,

University of Liverpool, Oct. 23rd, 1903. RUBERT BOYCE.

THE UNIVERSITIES' MISSION TO CENTRAL AFRICA.

To the Editors of THE LANCET.

SIRS,—I have been asked on behalf of the Bishop of Zanzibar (the Right Rev. J. E. Hine, M.D.) to make known the great need that exists in his diocese for the services of a fully qualified medical practitioner. In a letter received within the last few weeks the Bishop writes:—

> [illegible] help of Dr. R. Howard and his work, I hear, is always increasing as the people on the lake shores get to understand and to value the skilled treatment they receive at his hands. We want another [illegible] those who are in touch [illegible] qualified could bring [illegible] one might be found [illegible]

I should be most glad to give further and more detailed information to any who may desire it.

OSWALD A BROWNE, M.D. Lond.,
Member of the Medical Board of the Universities' Mission to Central Africa.
9, Dartmouth-street, Westminster, S.W., Oct. 26th, 1903.

SMALL-POX IN TASMANIA.

To the Editors of THE LANCET.

SIRS,—I observe in THE LANCET of Oct. 17th, p. 1132, a paragraph headed "Small-pox in Tasmania" I may mention that the outbreak to which you refer was confined entirely to the city of Launceston. It has now been altogether stamped out I have been advised by cable that the last case of small-pox occurred on Sept. 3rd and that the quarantine restrictions which had existed for a short time in Australasia against Tasmania have now been removed. As this subject may interest some of your readers I shall esteem it a favour if you will kindly insert the above information in your next issue.

I am, Sirs, yours faithfully,

ALFRED DOBSON,
Agent General.
Victoria street, Westminster, S.W., *Oct. 22nd, 1903.*

PROPOSED MEMORIAL TO THE NURSES WHO DIED ON ACTIVE SERVICE IN THE SOUTH AFRICAN WAR.

To the Editors of THE LANCET.

SIRS,—Nearly two years have elapsed since the conclusion of the war in South Africa and a duty still remains to be fulfilled which we venture to commend to the generous sympathy of the whole nation. While all honour has been accorded to the nurses who have returned from active service and acknowledgment has been made of the value of their work by the award of orders and decorations, nothing has been done to express the nation's appreciation of the devotion the work as at present organised in the flax-spinning mills where damp always prevails constitutes an insalubrious operation which is *injurious to* health.

---

[1] Transactions of the Royal Medical and Chirurgical Society, vol. xxix., p. 137.

[2] THE LANCET, August 5th, 1865, p. 141.

[3] Transactions of the Royal Medical and Chirurgical Society, vol. lix., p. 165.

1. Expresses the following desiderata: (*a*) That the age for admission in these mills or factories shall be raised to the extreme limit compatible with the economic situation and that the hours of labour shall be progressively reduced.

2. Invites the employers (*a*) to study with zeal all means of ameliorating the thermometric and the hygrometric condition of the spinning mills. (*b*) To indemnify by a suitable pecuniary allowance all workwomen who leave the works a fortnight before their confinement. (*c*) To install in or near to the mills crêches so that the mothers may go there to suckle their infants during the day's work.

The Dangers in Dealing with Skins

The next question dealt with the industries connected with the fur used for making felt and the extraction of bristles from the skins of animals. To pull out these hairs constitutes in itself quite a technique. The skin then undergoes another process called *secrétage* in French and "carotting" in English. It consists of dipping the skins into a solution of nitric acid and of mercury, then of drying them in an oven. Afterwards the nitrate of mercury formed has to be brushed off the dried skins. Dr. GLIBERT, the principal reporter on this question, showed how severe were the cases of mercurial poisoning that resulted and urged the necessity of periodical medical examination of the workers. Dr. T. M. LEGGE replied that such examinations were enforced in England and he had never seen in England such bad cases as those which Dr. Glibert had brought before the section. M. LECLERC DE PULLIGNY said that more energetic efforts should be made to find a substitute for mercury. In this, rejoined Dr. GLIBERT, the employers would gladly help for mercury was very expensive. A motion to this effect was at once adopted.

M. ALQUENBOURG (France) thought that whatever measures were taken should be as international as possible, for otherwise the nation that took the greatest care of its workpeople would be at a disadvantage when competing with other countries. The President of the Section, Dr. KUBORN, replied that the Belgian and French Governments were considering the advisability of attempting to induce the other Governments to join in constituting a permanent international hygienic institution having for its object the study of methods for the prevention of disease by means of an international agreement. The section by a vote approved of this effort.

Then the Congress adopted the following motion:—

> Besides the periodical medical examination of the workers, the noxious smoke or fumes produced during the operation of "carotting" must be removed by means of special local ventilation. The workers must wear a special dress when at work if they have to manipulate toxic substances. There shall be lavatories and dressing rooms at the disposal of the workers. The ventilation of the workshops shall be supervised with particular care.

Small Industries and Home Work.

Miss A. M. Anderson, H.M. Principal Lady Inspector of Factories, from the British Home Office; M. Fontaine, Director of the Office of Labour at the Ministry of Commerce, Paris; and M. van Overstraeten, Inspector-General of Labour from the Ministry of Industry, Brussels, were the reporters and the discussion was opened by the last named. He urged that the Belgian law of 1889 on the inspection of workshops and factories should be extended in its application to domestic workshops.

Miss ANDERSON gave a very lucid exposition of the law in England, showing how the smallest private dwelling or room could be treated as a workshop and inspected if anyone except members of the family living in the house was called in to work there.

M. LAUTER (Brussels) related how in his youth he had been compelled to work in a home industry, to which he was apprenticed, from six o'clock in the morning to the afternoon of the next day and had been 36 hours with hardly any rest. Not only was the labour excessive but the room was badly lighted and ventilated.

M. DRION urged that if the Belgian Government would only order an investigation appalling discoveries would be made as to the condition of the workshops of milliners and dressmakers.

Dr. BUYSE remarked that home industries were often not only injurious to the workers themselves but also to their neighbours. Thus, in Flanders skins were frequently prepared in private dwellings and the mercury employed could reach and poison neighbours. He thought that the employment of toxic materials in home industries should be forbidden. Professor DE WALQUE, however, considered that such a rule should not be enforced in a general sense as it would stop many industries that were not injurious—that of the photographer, for instance.

Mr. ADOLPHE SMITH spoke at some length on the sweating system and its obvious dangers to health and on the contamination of clothing made in private houses which could not possibly be converted into well illuminated and ventilated workshops. Nor was it possible to apply the laws and customs tending to elevate and to protect the worker if he was hidden away in a private house. There could never be inspectors enough to watch over these places even if they had a right of entry. It would be much more practical to build blocks, subdivided into small workshops which the workers could hire and where power and mechanical ventilation would be provided and inspection would be rendered easy. The great object was to keep the home sacred as a place of rest and the abode of the family and to attract the worker to workshops or factories built especially for the purposes of his trade.

Professor DE WALQUE interrupted with exclamations to the effect that it would be a great misfortune to do away with home industries and M. FUSTER spoke energetically urging that, on the contrary, modern effort tended to increase home industries. To drive the wife to the factory was to break up the family but if home work could be found for her then she might at the same time attend to her home and family while earning something to augment the joint income. With the help of electricity it would now be possible to supply power in private dwellings, thus reducing the necessity of going to a factory. This had actually been brought about in the Jura provinces, where the mountain torrents supplied the force to generate the electricity and this gave power in the cottages of the home workers.

M. VARLEZ protested that no one wanted married women to go to work in factories. In America there were no longer married women working in the mills. The object was to bring the man to the workshop where he could be watched, prevented from underselling other workmen, and made to earn enough to keep his wife instead of living on her earnings. A certain poetry might be associated with light forms of home work but in practice it led to cruel abuses. Public opinion could control the workshop and see to the hours and the wages being such as to render the preservation of health possible.

Miss ANDERSON here attempted to throw oil on the troubled waters by explaining that there were such enormous varieties in the nature of home industries that the different types of such work accounted for the various opinions that had been expressed in the section. Some of these home industries were very ancient and some were quite modern. Some industries would be better carried on by grouping the workers; others, on the contrary, could be undertaken by the isolated worker. The section evidently did not possess enough information to deal with the matter. There were crafts of an artistic nature that would be injured and the artistic qualities of the worker would be destroyed by the introduction among them of the factory system. No one rule could apply to the very different states that prevailed in different localities and trades.

M. MAMY (France) argued that the man should earn enough to keep his wife and thus the family life could be maintained but when this could not be done then the wife should get some home work to do and not go to a factory.

M. FUSTER remarked that there was an international association for the protection of labour. This association insisted that it was the duty of all mothers to suckle their children and that home life was to be promoted in every way. It would be very wrong for the section to vote against home work.

M. VARLEZ replied that the association to which M. Fuster had alluded did not deal with the question of women's work in general. Naturally all sanitarians opposed women going to factories; there was quite enough work for them at home if they attended to their children properly.

Some conversation ensued as to the Belgian lace makers. This was a home industry and a considerable quantity of carbonate of lead was employed in the "get up" of the lace. The fact that this was used within the family circle did not make it any the less poisonous. Then some confusion arose as to whether home work meant small workshops in private dwellings or places where only members of the same family worked together. Finally, and as this was the last day and this subject was the last on the agenda, the attendance gradually dwindled away. It seemed as if only those who were interested in the maintenance of home work remained, for the following motion, which was proposed by M. MAMY, was carried by 21 votes to six :—

> That the Congress desires that home work should be developed more and more by surrounding it with all the protective measures necessary for the security and the hygiene of the workers.

It must be confessed that this result and the discussion were disappointing. In England so much has been written and said on the question that it was natural to expect a better debate but evidently the question has not been so well studied on the continent. The French, it is true, were the first to enact a law against the sweating system and it bears the date of 1848 but the present generation of Frenchmen at the section seem to have forgotten what their fathers said on the subject and the law, though still on the statute book, has been allowed to become a mere dead-letter.

A Ministry of Public Hygiene.

Before the section finally adjourned it adopted a motion to the effect that hygiene should be taught in the schools of engineering. Then Dr. JULES FELIX (Brussels) read out the following :—

> If we consider the numerous discoveries and the increasing progress of experimental science as applied to public and private hygiene, [illegible] which cannot be separated as hygiene and as social economy when it is a question of insuring the strength and the health of the workers, the prosperity of nations, and the peace and happiness of humanity.

On being put to the vote, of the few persons still remaining in the section 12 voted for and 12 against. The chairman decided that the matter had better be dropped as, after all, he was not sure that it came within the scope and competence of the section. Thereupon the section dissolved, the members being glad to rest after their hard week's work.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Country Hospital for Chronic Diseases of Children.

THE governors at their meeting on Oct. 26th changed the title of this hospital to that of the "Liverpool Country Hospital for Children" and also made some important alterations in the rules. All this has been done in view of a very important change in the condition of the hospital. It has been done in the hope that the institution, which is at present located in the Children's Convalescent Home at West Kirby, will shortly have its own building at Heswall. Only £3000 stand between it and the accomplishment of that hope and the belief is strongly felt that this sum will shortly be forthcoming. The hospital is a home for neither cripples nor incurables, the object of treatment aimed at (by prolonged and judicious treatment in the fresh air of the country) being to prevent children becoming cripples. The ambition of the governors is to build an institution for themselves on the lines that experience has taught to be desirable. In 1900 they bought a site for the building which they propose to erect at Heswall. The committee has been promised £27,000 towards the requisite sum of £30,000. A donor of £5000 has made it a condition, however, of his gift that the £30,000 should be obtained before the commencement of building operations. The hospital authorities are now obliged to refuse admission to scores of suitable cases, cases in which disease does not stay its hand and which might become hopeless a year hence. The appeal for £3000 to enable the committee to commence operations at Heswall will surely not fail to have a generous response from the benevolence of Liverpool citizens.

Sanitation in Liverpool: a Year's Work by the Health Committee: Retirement of Two Medical Members.

At the concluding meeting for the year held on Oct. 22nd the chairman of the health committee spoke highly of the work of the medical officer's department during the last year. The health of the city was far better even than during the previous year. The death-rate had declined substantially and the lives of 1000 more people were saved this year as compared with last year. Everything pointed to a fuller decrease of the death-rate in the future. There had been a considerable diminution in the number of deaths from tuberculosis, which was very satisfactory. The infantile mortality had also decreased. The work of their female inspectors who were looking after the mothers and giving advice on domestic arrangements to the poor people no doubt accounted for this to some extent. The sale by the corporation of sterilised milk for infants was also a good work. During the summer months experiments were made on macadamised roads with a view to ascertain the effect of oil on roads in reducing annoyance from dust and these had proved satisfactory. They had disposed of nearly 300,000 tons of refuse by burning in the destructors. A few years ago this had been carried out to sea. This year only 55,000 tons had to be carried out to sea. The destructors also supplied heat for making electrical energy for the electric power and tramways committee. More dwelling houses had been erected in the city than in any previous year; it was evident that the prosperity of Liverpool was continuing. At the final meeting of the port sanitary and hospitals committee the retirement of Alderman Dr. Thomas Clarke, the chairman, was announced, as was also that of Mr. Alexander Murray Bligh who had served on the health committee for 27 years. Much regret was expressed by the members at the retirement of both gentlemen and warm tributes were paid to their devotion to the work of the committee.

Inaugural Ceremony of the University of Liverpool.

The Earl of Derby (the Chancellor), the council, and the senate have issued invitations for the inaugural ceremony of the new University which will take place at St. George's Hall in the afternoon of Saturday, Nov. 7th. Academical costume will be worn on the occasion.

Oct. 27th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Pontypool Hospital.

A SMALL general hospital was formally opened on Oct. 20th at Pontypool, a Monmouthshire town with a population of about 6000 persons situated in the centre of a mining district. Mr. Richard Coslett of Bristol, who died in 1895, bequeathed £1000 and an annuity of £100 for the establishment and endowment at Pontypool of a home for poor persons suffering from rupture. It was, however, found quite impracticable to carry out the testator's intentions strictly and with the consent of the Attorney-General Mr. Coslett's trustees were permitted to hand over the capital sum and the endowment to the trustees of the new hospital. There is accommodation in the institution for 19 patients. On the ground floor are two eight-bed wards, one for men and the other for women, a small accident ward, and a two-bed hernia ward. The site of the hospital was given by Mr. J. Capel Hanbury of Pontypool Park and the workmen of the district during the past two years have made a levy of 1*d.* weekly which has brought in about £1200 annually. The cost of the building was £7000 and that of the furnishing and ambulance was £1300. Nearly the whole of these sums have been subscribed and it is anticipated that the workmen's weekly pence, together with Mr. Coslett's endowment, will be sufficient to maintain the hospital. The medical staff will include the colliery surgeons practising in the district.

The Question of Tramps.

The Gloucestershire county council has for many years concerned itself with the question of tramps and at a meeting held on Oct. 20th a motion was unanimously passed requesting the Local Government Board to hold an inquiry with a view of establishing a more effective and uniform system of dealing with the evil of vagrancy. It was stated at the council meeting that in the county of Gloucester during the first nine months of this year there had been 40,761 admissions to casual wards, an increase of 7875 as compared with the corresponding period of last year.

One speaker said that the solution of the question was to be found not so much in the treatment of the vagrant as in the discovery how to educate the public not to encourage these lazy wanderers. So long as the public would give food and money so long would the tramp flourish. An illustration of the manner in which disease may be spread was given from Stow-on-the-Wold where a tramp was discovered to have small-pox. There was no isolation hospital in the union and temporary accommodation had to be provided, the cost of which with medical attendance and nursing amounted to £220. As a commentary upon this costly experience the recent action of the Monmouth board of guardians may be cited. For several months past the public vaccinator (Mr. T. G. Prosser) has by instruction of the board vaccinated or revaccinated tramps who have passed through the Monmouth workhouse but as the fees during the last six months amounted to £20 the guardians have decided to discontinue the practice.

Asylum Maintenance Charges.

The weekly charge per head made to the various Poor-law unions for the maintenance of patients in the Hereford City and County Asylum is now 9*s.* 7½*d.* and in the Somersetshire Asylum the charge is 9*s.* 4*d.* per head.

Plymouth Public Dispensary.

The annual meeting of the subscribers to this institution was held on Oct. 21st under the presidency of Mr. H. Lopes. The medical report stated that 3881 patients were treated during 1902, as compared with 3922 in the previous year; 765 of these were attended at their homes. The financial statement showed that the receipts amounted to £1024 and the expenditure to £1023. During the year Sir Massey Lopes had given £500 towards the endowment fund. The gross receipts of the provident department during the year amounted to £104, as against £114 in the previous year. It was decided on the recommendation of the committee to appoint an honorary gynæcologist to the dispensary.

SCOTLAND.

(From our own Correspondents.)

The Edinburgh New Fever Hospital.

Last week it was noted that the new fever hospital at Colinton Mains had been open for public inspection. It has now begun to be occupied. Fresh cases of scarlet fever have been admitted into it and also patients convalescent from scarlet fever from the old hospital in Infirmary-street No new cases of scarlet fever are to be received into the old building but cases of diphtheria and typhoid fever are still to be received there. It is, however, anticipated that in the course of six weeks or so the transference to the new hospital will be complete. There are at present 366 patients suffering from infectious disease in the hands of the public health authorities.

Epidemic of Scarlet Fever in Edinburgh.

Scarlet fever has assumed moderate epidemic dimensions in Edinburgh, this being a period of the year when it is likely to do so. In July there were 96 notifications of its presence; in August these had risen to 123 and in September to 143 During the month of September there were, in addition to scarlet fever, 60 notifications of diphtheria and 26 of erysipelas. During the same month 128 of the cases of scarlet fever were admitted into hospital and 46 of the cases of diphtheria.

Infant Milk Depôts

The subcommittee (of the health committee) on infantile mortality and the milk-supply of the city of Glasgow, after visiting the municipal depôts in Battersea, Liverpool, St Helen's, and Bradford, has submitted a report containing certain definite conclusions which are as follows. Infantile mortality has a definite relationship to (1) the feeding of infants; (2) personal care of infants by parents; and (3) housing accommodation Other elements enter into the problem but so far as municipal action is concerned these are the three main elements. It is clear that housing schemes, unless associated with efforts calculated to meet difficulties arising out of the first [illegible] be disappointing in [illegible] it is believed that [illegible] succeed in raising the quality, as regards purity, of the milk on which infants are fed they will at the same time educate and improve the sense of duty towards their infants on the part of parents. The mischief lies in polluted milk. The sources of the pollution are not only in unsatisfactory methods of milking and in storing and conveying the milk supplied but also very largely in dirty domestic conditions and particularly in carelessness in the use of feeding bottles. To attack successfully by municipal administration all the sources of pollution is at present impossible but the ideal of health administration is a pure milk-supply which needs no sterilisation and towards that end all efforts should be directed. Meanwhile the best that can be done under existing conditions involves sterilisation of the milk. The subcommittee therefore recommends that the corporation should agree to the principle of supplying milk for infant feeding in poor localities. This involves (1) the setting up of an establishment for the preparation of the milk supplied, modified and sterilised according to requirements, and (2) depôts for the sale of the milk unless supplied through milk-dealers to whom an allowance for retailers' profit would require to be made. It is suggested that the experiment should be made in three or four of the districts where the infantile mortality is high. The price at which the milk could be sold consistent with reaching the poorest would be no more than is at present paid for ordinary milk, and in any case, even were it necessary, a small charge upon the health-rate would be justified by the result. The health committee has accepted the report and has recommended that it should be adopted by the corporation and that the health committee should be empowered to carry the business through.

The Clyde Port Sanitary Authority.

The special subcommittee of the Glasgow corporation, the members of which visited several seaport towns in England and ascertained the procedure followed out in these places, has issued its report in which it recommends—

1. The medical officer of health to be the chief medical officer of the port and responsible to the port authority in every matter and way in which he is now responsible under the Acts and regulations made by the corporation of the city for the proper discharge of his duties as medical officer of health for the city.

2. The chief sanitary inspector to be the [illegible] the port and responsible to the port authority [illegible] in which he is now responsible under the Act [illegible] the corporation of the city for the proper [illegible] sanitary inspector for the city.

3. The clerk of police to be clerk to, and law adviser of, the port local authority, to issue statutory notices when required, carry on any negotiations or correspondence arising out of questions of detention of vessels, damage to, or destruction of, cargo, or any other claim or matter arising out of the operations on board infected vessels, and to act as agent for the port authority in any court proceedings which may be found necessary.

Small-pox in Glasgow.

There has been an outbreak of small-pox again in Glasgow. On Oct. 16th there were six cases and on Oct. 23rd 21 cases. The outbreak originated from a labourer who on Sept. 12th travelled by train to Glasgow, staying that and the following night at one of the model lodging houses Thereafter he went to another model lodging-house where he sickened and where subsequently six cases occurred among persons sleeping in the same dormitory. No fresh cases supervened until Oct. 20th when a series began to appear in the model lodging-house in which the man slept first. All the cases which have occurred up to the present have been traced to the same source. Summary measures have been taken throughout; these have consisted in the immediate removal of all cases to the hospital, thorough disinfection, and revaccination. No new inmates have been admitted into either of the lodging houses where the cases occurred unless they had been recently revaccinated or submitted themselves to revaccination.

Aberdeen University Medical Society.

The opening lecture on Medical Ethics was delivered on Oct. 23rd by Dr. Angus Fraser to a very large audience. Professor J. T. Cash presided and in introducing the lecturer referred to the eminent position held by him in the medical profession and to his special fitness for delivering such an address. Dr. Fraser referred to the necessity of young practitioners at the beginning of their professional career having some definite knowledge of the relations which should guide their intercourse with other medical men and with their patients. Medical men ought to "do to others as they would that others should do to them"—e.g., a medical man was not entitled to take over a patient to whom he had been introduced while acting as a substitute or as a consultant, not even for a different or a subsequent illness unless in special circumstances. In a small town it was more difficult to stick to that rule, but the practitioner ought to inform the recent medical attendant of his being called in and, as a general rule, also to tell the patient to pay any fee due to the former physician. This engendered friendly feeling which was usually reciprocated. On no account ought one medical man to call in question the treatment adopted by another to any patient—if he thought previous treatment should be changed then let him do so without drawing any special attention With regard to patients he advised the medical man to "possess himself of an irresistible, indestructible optimism." If there were any serious case he might tell a relative in the event of death and future recriminations. He strongly advocated the great benefit to be derived by a newly fledged medical man in taking a house surgeonship in any general hospital for a short period or, failing that, he recommended an assistantship under an experienced practitioner. He then gave several useful hints as to the best way to begin practice for oneself, particularly referring to the bogus concerns where a medical man worked up a practice, more or less non-paying, in a few years and then offered it for sale preparatory to shifting to pastures new and repeating the dodge. At the close of the address a vote of thanks to the lecturer was proposed by Mr. James Clark and a similar compliment to the chairman was moved by Dr. Fraser, both of which were heartily accorded.

Oct. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Poor-law Medical Service.

AT the meeting of the Cookstown board of guardians on Oct. 24th it was decided after a long discussion to increase Dr. C. H. P. D. Graves's salary from £50 to £90. Dr. Graves is medical officer of the union infirmary and fever hospital and this increase simply brings his pay up to that of his predecessor and it is only after 15 years' service that the salary has been brought up to what it formerly was. I am glad to report that this has been done but sorry to note that one of the guardians who supported the increase said he did so all the more heartily as Dr. Graves had not joined the Irish Medical Association which is battling so hard to improve the wretched position of the Poor law medical officers. At the same meeting Mr. H Harris's application as medical officer of Stewartstown for more than 20 years for an increase of salary was not only refused but his letter was treated with great contempt, being marked "read." His work has greatly increased as medical officer to the rural district council and, as he stated in his letter of application, "his salary would not pay cab hire." The ways of the guardians are at present peculiar.

Annual Dinner of the Cork Medical and Surgical Society.

The annual dinner of the Cork Medical and Surgical Society was held on Oct. 24th. There were about 40 persons present, including several guests The chair was occupied by the President, Dr. J. Cotter. The toasts were "The King," "The Cork Medical School," "Our Guests," and "The Officers of the Society." Professor J. J. Charles and Professor W. E A. Cummins replied to the toast of the Cork Medical School. Professor Charles referred to the numerous important posts occupied by past students of the Queen's College and the desirability of maintaining the medical school at its present high standard. "Our Guests" was responded to by Sir Abraham Sutton, high sheriff, and Mr. O. C Cowan, chief engineering inspector to the Local Government Board. The high sheriff referred to the rumoured proposed settlement of the University question and commented on the loss it would be to the people of Cork if the medical school were swept away as the result of any political manœuvring. Mr. Cowan expressed his admiration for the medical profession and his sympathy with the grievances of the Poor-law medical officers but pointed out that unjust odium had attached to the Local Government Board, as its action is necessarily limited [illegible] the Treasury. A nt [illegible] of the evening and [illegible] late hour.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Remuneration of Assistants at Surgical Operations.

IN general the remuneration of medical men who act as assistants at surgical operations is very small in comparison with that of the operator himself, but this seldom leads to disputes because in most cases the surgeon brings men who have studied under him. Exceptions, however, sometimes occur and an important judgment has just been delivered on this subject deciding that the surgeon is not to have the only voice in the matter. This judgment is founded on the following considerations When the medical man who acted as assistant has only been engaged on work of an ordinary character such as does not require the possession of a diploma, and might in fact have been done by almost anybody, then it is reasonable that the surgeon should decide how much shall be paid and that his decision shall be final, but the case is different when the assistance was indispensable to the success of the operation and was such as only a medical man could give. In these circumstances the courts may intervene if the surgeon and the assistant required by him cannot come to an understanding. In the case which led up to the decision just mentioned the surgeon had charged the patient an inclusive sum to cover both his own fees and those of his assistant. The surgeon's own fees were calculated on the basis of the patients' presumed standing, the difficulty of the operations, and the standing of the operator; the fees of the assistant were calculated in the same way, regard being had to the relative positions of the surgeon who operated and of the assistant who administered chloroform. The court ordered the surgeon to pay his assistant the sum of 270 francs (£10 16*s.*), considering that the latter was a practitioner of repute and that he had evidently been selected on the ground of his admitted experience.

The Causes and Treatment of Rheumatism.

At a recent meeting of the Academy of Science M. Pénière discussed this question He reminded the meeting that the researches of Bouchard had shown that ordinary healthy urine contains toxins and still more that which is in a pathological condition These poisons are eliminated without danger to the health of the body through the action of the epithelium which lines the urinary passages. This layer of epithelium forms a fragile barrier but one which is quite sufficient against the absorption of these products. If, however, this protective layer is injured in any way absorption of the poison takes place into the general circulation. It is this which produces rheumatism. The product which is reabsorbed is a ferment analogous to, if not identical with, the fibrin ferment studied by Schmidt and A Gautier The epithelium lining the ureter is that which is particularly concerned in the absorption; visceral congestion provoked by cold or damp, erosion brought about by calculi or the passage through the ureter of toxic substances, wounds of the surrounding tissue, straining, and pressure brought about by the intestines or by the psoas muscle may all cause a desquamative ureteritis which is a forerunner of rheumatism This desquamation manifests itself at the beginning of an attack of rheumatism by a high coloured urine As regards therapeutics in rheumatism it is necessary in accordance with this pathogenic view to restore the epithelium of the ureter and to destroy or else to neutralise the ferments Some antiseptic must therefore be sought for by which the ureter can be freely irrigated without inconveniencing the stomach, the kidneys, or the general health. M. Pénière generally uses a combination of various resins, among which is that obtained from cubebs.

Sleeping Sickness.

On Oct 20th M. Blanchard showed to the Academy of Medicine three negroes suffering from this strange disease which on the African continent is the cause of a higher mortality than either plague or cholera. These three negroes had been brought from the Congo by M. Brumpt who is the assistant of M. Blanchard. At Brazzaville M. Brumpt had seen 38 cases of this disease. The unfortunate sufferers from it fall little by little into a state of sleep and at the end of a longer or shorter period die. The three patients exhibited to the Academy of Medicine showed oscillations of the head and erratic movements of the eyes and had a very peculiar air of stupidity and heaviness.

The disease is due to the presence of a protozoon belonging to the genus trypanosoma which breeds in the cerebro-spinal fluid of the patients.[1] It is not yet known how the trypanosoma comes to pick out this particular place of dwelling but there is another African disease affecting the same regions called Dutton's disease. In this complaint there is no slumber although the parasite appears to be the same as in sleeping sickness, but in Dutton's disease the parasite remains in the blood instead of passing, as in sleeping sickness, into the cerebro-spinal fluid. Sleeping sickness only attacks the black races. Dutton's disease attacks both whites and blacks alike. It is well known that Dutton's disease is due to the bite of the tsetse fly which apparently conveys the trypanosoma from one patient to another by its bite. In general this fly only bites animals which it kills very rapidly by being the cause of the disease called nagana. M. Blanchard asked if sleeping sickness could be a cerebro-spinal form, which was proper to the negro race, of Dutton's disease. He also asked if it was a human form of nagana and if it was the same variety of the tsetse fly which produced the two diseases. In any case, the bite of this fly is necessary for the spread of the malady, for negroes suffering from this disease who have been taken to America have never been the cause of the transmission of sleeping sickness. M. Brumpt has tried to inoculate this disease into animals but his experiments were without result in rats, mice, and guinea-pigs, although it is possible that the incubation period may be very long. He was, however, enabled to inoculate a monkey which died with all the symptoms of sleeping sickness but unfortunately no histological examination was made.

The Anti-Alcohol Congress.

The First National Anti-Alcohol Congress was opened on Oct. 26th in the large theatre of the Faculty of Medicine, M. Casimir-Perrier being the acting President. In connexion with the congress there was an anti-alcohol exhibition which was held in the hall of the Pas-Perdus.

The Disinfection of Bathing Cabins.

In connexion with the report drawn up by M. Duguet the council of hygiene of the department of the Seine has just laid down measures of disinfection which must be taken in the case of bathing cabins. The floor of the cabin must be made of some impermeable substance. The walls and the seats must be smooth and covered with either tiles or cement. The seats and the furniture should be either painted or else covered with some material which can be easily washed. The pieces of cork which it is the custom to give a bather to stand upon when he comes out of his bath must be covered with a napkin which is to be changed for each bather and every time that such napkin is used it must be thoroughly washed in soapsuds or else sterilised in a stove at 100° C.

Oct. 27th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Myopia in School Children.

Dr. A. Steiger of Zürich in a paper which appeared in the last number of the *Swiss Journal for School Hygiene*, and which is sent to all medical men and schoolmasters and schoolmistresses of the Swiss State schools, discusses the relation existing between myopia and the faulty positions in which children sit when at school. A great number of children are sent to him by schoolmasters on the ground of supposed shortsightedness, the reason apparently being that they assume such awkward postures that the masters at length come to the conclusion that their eyesight must be defective. An examination of 22,941 children aged six years has, however, proved that myopia is very rarely at the root of the evil, for of this number only 222—i.e., less than 1 per cent.—were suffering from myopia. An examination of 2994 school children in Zürich during the year 1902 showed that 485 of them had defects of vision as follows: hypermetropia, 26; myopia, 28—i.e., 1 per cent.; astigmatism, 259—i.e., 8·5 per cent.; paralysis of accommodation, 50; maculæ of the cornea, 21; various affections, 17; and diagnosis indefinite, 84. The schoolmasters are instructed to divide the children into three classes—namely, those who have normal vision, those who have abnormal vision, and, lastly, the doubtful cases. These superficial examinations may be made by any fairly educated person but in the majority of cases a thorough investigation by an ophthalmic surgeon is necessary in order to ensure a correct diagnosis. Of course seating themselves improperly, a practice which Dr. Steiger remarked in at least 25 per cent. of all the school children, is productive of shortsightedness.

Workmen's Compensation and Self-inflicted Injuries.

Dr. E. Patry of Geneva has published his startling experiences of traumatic œdema of the back of the hand, a "new disease" which was first described by Dr. H. Secretan in the *Revue Médicale de la Suisse Romande* for July, 1901. Dr. Chenissi of Montpellier has also written on the subject. Dr. Patry, who saw 11,725 accident cases at the Geneva Cantonal Hospital during the period 1896-1902, encountered the first case of traumatic œdema in 1899, six cases in 1900, and 42 in 1901 and 1902, a fairly remarkable increase. The first two patients were awarded £52 as compensation under the Workmen's Act, but the later cases had to be contented with sums varying from £15 down to £2 10s. Careful investigation went to prove that probably the great majority of the lesions were deliberately brought about for the purpose of being used in claiming compensation. Dr. Patry concludes this from the fact that the number of attacks rapidly increased after considerable compensation had been paid, that the cases occurred only among Italian workmen who either came from the same district or occupied lodgings together, that out of 48 cases the left hand was affected 34 times, that the men eventually accepted small sums as compensation, and that the majority of cases occurred in September, October, and November when the men were out of work. Self-inflicted injury could be brought home in one case only, the man having caused the œdema by repeated knocks with a hammer. Dr. Patry concludes that the etiology of this new disease is to be looked for in the compensation clauses of the Workmen's Act.

Zürich, Oct. 24th.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

Health of New York City for the Year 1902.

IN the year 1902 New York reached its lowest recorded death-rate. The mortality-rate of 18·75 per 1000 was not only the lowest known in the city as a whole but each of the five boroughs had also its lowest recorded death-rate.

Provision for Consumptives in New York City.

During the past few years New York has awakened to the need of properly caring for those suffering from pulmonary tuberculosis within her borders. It is now understood by the more intelligent citizens that the consumptive, if allowed to remain in the crowded districts, is a menace to the entire community. Self-preservation is said to be the first law of nature and acting upon this ancient axiom the municipal authorities of New York have taken steps to isolate individuals who are likely to spread tuberculosis among their families and neighbours. The American *Review of Reviews* for October, in an article treating of the progress made in municipal affairs in New York during the past two years, refers to the provision made for consumptives as follows:—

> Two buildings have been completely altered to fit them for new purposes. One of these formerly occupied by a State hospital for the insane has been utilised, together with other unaltered buildings, as a hospital for consumptives. This was opened Jan. 31st, 1902, and provides separate quarters and special care for all male consumptives in the care of the department in the boroughs of Manhattan and the Bronx, and for female consumptives for all boroughs. 440 patients were in this hospital on August 1st. Eight tents accommodating 110 patients have been erected, in which there will be abundant opportunity for open-air treatment. It is intended to keep these tent cottages open during the coming winter, as is done in similar tents occupied by insane patients on Ward's Island. It has also been decided to erect an adequate municipal sanatorium for incipient cases, under the management of the board of trustees of Bellevue and allied hospitals.

New Water-storage Plan for New York.

Although the city of New York now enjoys what Londoners would consider a most ample supply of water its citizens are not satisfied and plans are afoot to provide an amount of water which may be termed superabundant. A commission of experts has been examining into the sources of water for some time and is expected to make its report to the mayor shortly. It is said that in this report six different propositions will be laid before the city with regard to water-supply conditions. Three of these will deal with the Croton watershed, whence the water of the city is now derived, one with a ramification of the old Ramapo idea, a fifth with the storage dam capabilities of the Adirondack region, and the sixth with a Catskill mountain storage proposition. It has been found that by damming a section in this district an area of eight square miles would be formed as a natural reservoir and at a comparatively small expense. According to present estimates the construction of the plant would take ten years, when the city would have one of the best water plants in the world and at a very small cost.

---

[1] Vide THE LANCET, June 20th, 1903, p. 1735.

Health of the American Army.

The annual report of the Surgeon-General of the United States Army has been published recently by the War Department. Brigadier-General Robert M. O'Reilly, the Surgeon-General, devotes a large portion of his report to a consideration of the health aspects of the American army of occupation in the Philippine Islands. The death-rate of the American negro troops and of the native Filipinos serving under the Stars and Stripes was almost 60 per cent. greater than among the white troops. The entire army at home and abroad during the period covered by the report showed for the white troops an admission-rate of 17·06 per 1000 and a death-rate of 14·40. The negro troops had 18 97 admissions per 1000 and a mortality-rate of 24·11 deaths per 1000, and the Malay Scouts 17·07 admissions and 24·04 deaths per 1000. Asiatic cholera appeared to be far less deadly among the white soldiers of the army than among the negroes and Filipinos. The white soldiers had 4·72 cases and 2·83 deaths in each 1000 of strength, while the negro regiments showed 15·68 cases and 7·96 deaths per 1000, and the Filipino troops 16 68 cases and 10 15 deaths per 1000. General O'Reilly, however, explained that these figures were largely due to the fact that there were a large number of white soldiers in the United States who were not exposed to cholera and that when these circumstances were taken into account the rates for the different races do not exhibit a great difference. Beri-beri was especially deadly among the native soldiers, causing an admission-rate among the Malay Scouts of 123·92 per 1000 and a death-rate of 6 01 per 1000. This disease scarcely affected the soldiers of white colour and the negroes were attacked by it to quite a slight extent. Alcoholism showed the other side of the picture. Out of 5000 Filipino soldiers but three were treated for this condition, while the rate for white troops was 24·78 per 1000, for negroes 11·70 per 1000, and for Malay Scouts 0 62 per 1000. The Surgeon-General called attention to the fact that yellow fever had been practically driven out of United States territory and declared that "a little concerted action on the part of the countries whose ports still harbour the disease, and the most terrible malady of the two American continents will undoubtedly disappear for ever." It is also pointed out in the report that the summer of 1902 energetic measures were taken at army ations in the United States situated in malarious districts exterminate mosquitoes. The work was fairly successful ad was continued during this season. The methods of preention put into force were the use of petroleum on large odies of stagnant water and draining, clearing underbrush, c. 20 soldiers fell in action in the fiscal year ending une 30th, 1903, and there were 31 suicides and 12 homiides. On the whole the report is satisfactory, especially hat part which deals with the health of the white troops in he Philippine Islands.

The Progress of Medical Education in the United States.

A recent statistical inquiry was made by the *Journal of the merican Medical Association* to determine the condition of edical education in the United States at the present time. rom this article it appears that there are 154 medical colleges hich are chartered to grant the degree of M.D.; of these 21 are regular, 19 are homœopathic, ten are eclectic, three re physico-medical, and one is national medical. In addition here are three schools which give instruction in the first two ears' work, making a total of 157 institutions devoted to the eaching of medicine. The number of medical students in the chools during the year ending June 30th, 1903, was 27,615, istributed as follows: 24 930 were at the regular schools, 498 at the homœopathic, 848 at the eclectic, and 339 at the ondescript schools. There was an increase in the attendance t the regular schools of 52 over that of last year and an increase over that of the year previous of 1024. In the homœopathic schools there was a decrease of 119 below that of 1902 and of 185 since 1901. The number of students in the eclectic schools increased in the past year, 848 being registered, against 765 in the preceding year and 664 in 1901. The attendance upon the nondescript schools also increased—viz., 98 over that of last year and 115 over that of 1901. The total number of graduates in medicine for the last year was 5698, an increase of 699 over that of the preceding year. The ratio of schools to population of the cities in which they are located is very striking. New York, with 3,500,000 inhabitants, has seven schools, while Chicago, with 1,500,000 inhabitants, has 14 schools. Until the year 1895 no educational qualification was required by any school higher than graduation from an ordinary high school. In that year the Johns Hopkins Medical School announced that to gain admittance to that school applicants must possess the Bachelor's degree in arts and sciences and also certificates showing a year's work in biology, chemistry, and physics, and must give evidence of the possession of reading knowledge of French and German. Though these requirements were strongly opposed by the schools and the profession on the ground that they were almost prohibitive to the class which generally applies for admission to the schools the standard was maintained by the Johns Hopkins school with steadily increasing classes. But what is most interesting, the sentiment is gaining ground that the schools must have a high standard of admission if they would do full justice to the profession. The time is apparently near at hand when the schools will raise the standard of educational qualification for admission to some position not greatly inferior to that of the Baltimore School.

The Legal Status of "Faith-cure" in New York.

A case has recently been decided by the highest court of this State which determines the legal status of "faith-cure." A Christian Scientist was convicted by a jury for intentionally failing to provide medical aid for his child suffering from broncho-pneumonia and was sentenced to 500 days in gaol and to pay a fine of $500. The law provides that "a person who wilfully omits without lawful excuse to perform a duty, by law imposed upon him, to furnish food, clothing, shelter, or medical attendance to a minor is guilty of a misdemeanour." The question as to the meaning of "medical attendance" is determined by the court to be "the authorised medical attendance prescribed by the statute" and according to the statute only a legally qualified practitioner of medicine could be a medical attendant. Now a legally qualified practitioner of medicine in this State is a person who is a graduate of a chartered medical school and who has passed the State medical examining board. This decision settles for the present the legal status of the "faith-cure" scientist and the fate of those parents who neglect their children in regard to providing medical attendance on the occurrence of sickness.

Oct. 19th.

Obituary.

ROBERT JOHN GARDEN, M.D. ABERD.

THE death is announced on Oct. 23rd at Coynach, Aberdeenshire, of Dr. R J. Garden. Since his retirement from the office of senior surgeon of the Royal Infirmary, Aberdeen, three years ago Dr. Garden had been living in retirement at Coynach, the gradual failure of his eyesight, ending in total blindness, having precluded him from the practice of his profession. He had not been in good health for some time, his strength having rapidly given way under his enforced confinement Dr. Garden was a son of the late Mr. James Garden, advocate. He studied medicine at the University of Aberdeen, graduating M.B. and C.M. in 1872 with highest honours, after a brilliant curriculum in which he took the leading places in all his classes. To surgery he always had a special leaning and was class assistant to Professor Pirrie during the session 1870–71,
while during his fourth year
house surgeon at the infirmary
the great medical schools of
for two years, after which he settled down to practice in Aberdeen in the year 1874. Almost immediately he was appointed to the dispensary and held office there till 1880. In 1876 he was appointed as fourth surgeon at the

Births, Marriages, and Deaths.

BIRTHS

BRUCE PAYNE.—On Oct. 25th, at Melville, Shepherdswell, the wife of Edward Bruce Payne, M.R.C S., L.R.C.P., of a daughter.

CARRUTHERS.—At 12, Rose Terrace, Perth, N.B., on the 12th inst., the wife of D. A. Carruthers, M.B., C.M , D P.H., of a daughter.

GOODCHILD.—On Oct. 26th, at 9, Highgate-road, N.W., the wife of N. John Goodchild, M.R.C.S., L.R.C.P. Lond., of a daughter.

WOAKES.—On the 27th Oct., at 79, Bickenhall-mansions, Gloucester-place, W., the wife of Claud Woakes, of Harley-street, of a daughter.

MARRIAGES

HARRIS—CUMMINS.—On Oct. 24th, at St. George's Church, Bloomsbury, by the Very Reverend the Dean of Worcester, assisted by the Rev. R. B. Tollington, M.A., vicar, Henry Arthur Clifton Harris, M.R.C.S England, L.R.C.P. London, eldest son of the late Henry Harris, M.R.C S. England, to Lillian Maud Cunard Cummins, L.R.C.P. Ireland, L.R.C.S. Ireland, elder daughter of the late William Alves Cummins.

SAFFORD—BADCOCK.—On Oct. 28th, at Dum-Dum, Bengal, India, by the Rev. Cogan, D.D., assisted by the Rev. C. H. Barlow, M.A., vicar of Barrackpore, Arthur Hunt Safford, Captain, Royal Army Medical Corps, second son of Arthur Herbert Safford, to Dorothy Jeanne, elder daughter of A. P. Badcock. (By cable.)

STEELE-PERKINS—HARRILD.—On Oct. 27th, at Holy Trinity Church, Sunningdale, John Shirley Steele-Perkins, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C P. Lond., to Elsie Charlotte Ann, younger daughter of Horton Harrild.

DEATH.

WILLS.—On Oct. 16th, at 232, Old Kent-road, London, James Wills, M.D., aged 49 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CIGARETTE CRAZE.

To the Editors of THE LANCET.

SIRS,—With reference to the harmful results popularly attributed to cigarette smoking I think all critics on the subject seem to lose sight of the fact that the average cigarette smoker will get through about twice as much tobacco in the week as the pipe smoker—at least, this is my experience, and I have observed the matter closely both at home and abroad. Everything tends to this condition of things: the ease and *facility with which a cigarette can be smoked and obtained compared* with a pipe, the number of occasions on which a pipe is not permissible is also in favour of the cigarette, and of course, the fascination of the actual act of smoking is in itself a great factor in conducing to the craze. I suppose any subject like this would be incomplete without figures and statistics and I consequently give a few. A pipe smoker who consumes an ounce of tobacco per diem, that is seven ounces a week, would be considered a very excessive smoker, and three and a half ounces a week may well be put down as the average. One of the most popular brands of cigarettes weighs 14 to the ounce and another 20 to the ounce, and a very excessive cigarette smoker would consume between 250 and 300 cigarettes in a week, and this is no uncommon occurrence by any means. If he smoked the brand first named he would consume 21 ounces of tobacco per week and if the [illegible] several men who get through 300 Egyptian cigarettes per week all the year round, which at a low estimate is two ounces of tobacco per diem, and apparently do not suffer any appreciable disadvantages from doing so, but I never met the man yet who smoked two ounces of tobacco a day with a pipe, and if there are such I am sure they are more likely to suffer than the cigarette smoker for one reason alone, the latter escapes all the disagreeable results of a foul pipe. Like [illegible] quality [illegible]

JOHN J. SCANLAN,
late Surgeon-Captain Imperial Yeomanry (South Africa).
Station Hospital, Fermoy, Oct. 21st, 1903.

⁎⁎⁎ Another correspondent ("M M.") writes that "the deleterious effect of cigarettes is in some degree due to the bleaching processes which the light coloured tobaccos undergo and to the presence in them of nitre and other chemicals," and adds that "it is significant that all the great cigarette-smoking peoples, with the possible exception of Russians [and he should have included Turks and Egyptians]—i.e., those of Spain, Portugal, France, Italy, and South America—invariably smoke cigarettes of dark-coloured tobacco." Virginia cigarettes he regards as much more harmful than those made of dark tobacco; for example—Algerian, Brazilian, or West Indian cigarettes. We are not aware that tobacco is artificially bleached, whilst nitre is a natural constituent of the leaf. On the other hand, it is quite possible that there is a difference between *the character of the smoke of light and of dark tobacco* We have known professional tasters of wines and spirits to be great smokers of cigarettes made of dark tobacco: the light-coloured tobacco, they assert, destroys the discriminating sense of the palate —ED. L.

REFUSE DESTRUCTORS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers furnish data showing the effects of refuse destructors on the vital statistics of towns where they have been in use for a period of sufficient duration to show results?

I am, Sirs, yours faithfully,
Aberystwyth, Oct. 26th, 1903. T. D. HARRIES.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—In reply to "General Practitioner" in THE LANCET of Oct. 10th, p. 1066, I may briefly relate my motoring experience. I have been for more than six years thoroughly conversant with the mechanical parts of many of the cars on the market, having been the owner of four during that period. My experience of the one suitable to a medical man of moderate means, and one particularly adapted to his special requirements, may prove a guide in determining the purchase of a reliable car. During the last seven years improvements have been many and varied. Cars are more reliable, structurally are more perfect, and the designs are more pleasing. My purchase of a little French car, the "Dorey," and, after four months' experience, a tour of 1500 miles through Scotland, Wales, and the Lake District have given me every satisfaction. The following are the particulars in brief:—It was made in *Paris*, tube frame entirely suspended, 6 h.p. *Di Dion* motor in front, with radiators, throttle on exhaust, water cooled, driven by friction pump on fly wheel, three speeds (8, 12, and 24 miles) and reverse, the third speed always in mesh and direct drive, live axle, four equal artillery wheels, pneumatic tyres (760 by 85), body in wood and aluminium, side lever for change of speeds, inclined pillar, wheel steering, three brakes, petrol tank (two and a half gallons) and lubricating tank, in front on dash, Di Dion carburetter, no chains, bands, &c., two bucket seats in front, and room for another seat behind. I have a hood fitted which renders one independent of the weather. There is a full capacity for luggage in the rear. The price is £167 delivered in London; without tyres, £151. Extras are hood, detachable tonneau, and seat in rear. To avoid any unnecessary correspondence I should be pleased to allow any medical gentleman a trial run here by appointment, the only expense being the driver's fee. There is an expert motor-car driver in this town whom I can confidently recommend On all sorts and conditions of roads I find I can do my work in half the time as compared with a horse, averaging about 12 miles a day at a cost of about 3*s*. 6*d*. per week for petrol and oil. Under favourable conditions and good roads the car runs 70 miles on two gallons of petrol. I consider, speaking roughly, that 20 per cent. *ought to be allowed for depreciation per annum. Moreover, the* amount of depreciation depends so much upon how the car is looked after, driven, and intelligently used.

I am, Sirs, yours faithfully,
E. PEACOCK, M.R.C.S. Eng., L S.A.,
Nuneaton, Oct. 19th, 1903. Medical Officer of Health.

KING CHARLES II. AND THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

To the Editors of THE LANCET.

SIRS,—In the summarised account of the benefactors of, and benefactions to, the Royal College of Physicians of London at the opening of Dr. W. H. Allchin's Harveian Oration in THE LANCET of Oct. 24th, p. 1141, there is an incidental reference to the visit of King Charles II. to the College in 1665. The *following quaintly phrased* allusion to that event by a contemporary writer may perhaps be of sufficient interest to merit insertion in THE LANCET:—

> *The K. visits the Colledge of Phyricians of London, April 15, 1665.*—Nor was the King so wholly taken up with the thoughts of the approaching War, but that he also minded other affairs, and his innocent diversions; he therefore on the fifteenth of *April* visited the famous *Colledge* of Physicians of *London*, and was received very honourably by the *Doctors*.
>
> There he saw the Marble Statue of *Harvey* the chief Pilot of the Blouds Circulation; and heard the *President Ent*, with [illegible] natomy, [illegible] *Bates*, [illegible] ter his *chief Physician* since; and *Glisson*, excellent in *Medicine* and Philosophy; and successful *Micklethwait*; and much-esteemed *Cox*; and *Scarborough*, accomplished in all Natural Philophy, [*sic*] and no less famous amongst the Muses; with *Wharton* the Secretary of the *Glandules*; and acute *Merret*: besides many others eminent in the Art of *Curing*; to whom at length were associated, *Willis* the great Restorer of Medicine, but of too short a life, with *Lower* and *Needham* who have illustrated the *Faculty* by their Writings.

The book from which the above is taken was published in 1685 and consists of three parts Part I. (first published anonymously in 1651) and Part II. were written, in Latin originally, by Dr. George Bates, "Principal Physician to K Charles the I. and K. Charles the II.," under the title of "Elenchus Motuum Nuperorum in Anglia: or, a short Historical Account of the Rise and Progress of the Late Troubles in England." Part III., the work of "Tho. Skinner, M D.," at p. 87 of which the quoted sentences may be found, bears the title, "Motus Compositi: or, the History of the Composing of the Affairs of England by the Restoration of K. Charles the Second, and the Punishment of the Regicides; and other Principal Occurrents to the year 1659." This part also was first published in Latin, presumably between 1669 and 1676, seeing that Sir George Ent who held the Presidentship of the College during the period 1670–75, is styled therein "the President Ent."

I am, Sirs, yours faithfully,
Oct. 26th, 1903. W. R.

THE MOTOR-CYCLE IN MEDICAL PRACTICE.

THE subject of motor-cycling for medical men—and especially for those in country districts whose practices are scattered over large areas—is one which has not received anything like the attention which the possibilities of this comparatively inexpensive and rapid method of transport would seem to warrant. "A Country Doctor," in the current issue of the *National Cyclists' Union Review*, relates his experience of motor-cycling in his practice and is enthusiastic over the success of his efforts since he discarded the use of horses in June last year. Certainly "A Country Doctor" makes out a strong case for the more general adoption of the motor-cycle by medical men, and on the whole we are inclined to think that there is much to be said in its favour. We should have liked a little more information on one or two points—i.e., as to the steps taken, when riding in the rain, to prevent the electrical connexions getting wet and thus becoming a source of short-circuiting; the weight of the motor-cycle as well as the size of the frame and the size of the wheels; and "A Country *Doctor's" own height and weight—important factors generally, but* particularly so when the purpose for which the motor-cycle is used is considered. Our own view is that for the average-sized man and on the average road the practical machine is one weighing not more

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only acts as a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières Paris.

An Address

ON

MEDICINE AND SCIENCE IN THE MODERN UNIVERSITY.

Delivered at the Opening of the New Medical School of the University of Toronto on Oct 1st, 1903,

BY C S SHERRINGTON, M A, M D CAMB, F R S,

HOLT PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LIVERPOOL

PRESIDENT LOUDON, DR REEVE, LADIES AND GENTLEMEN,—Believe me, it is a difficult thing for a stranger, even at your invitation, to address you on an occasion like the present So many significant events crowd in upon him and time for reflection is needed to weld into a connected whole the impression he would wish to offer to you Not that the growth and doings of this University have not been followed and watched with interest by us in the old country; on the contrary, your activity has been felt not only as a matter of mutual congratulation but as a spur to arouse us to effort in our own similar pursuit of educational aims But the stranger coming among you necessarily feels the shortcomings of his acquaintance with the details of these academic enterprises you have taken in hand One advantage however, is his His view, gained from a distance necessarily has freedom and truth of perspective that may give it a value in your eyes Some things lose by perspective Some things large when close to hand dwindle when viewed from afar Not so Canada. The perspective given by the width of the Atlantic is but an appropriate setting across which to view her greatness and her far reaching activity And this event, this academic celebration, this *dies festus* in your University to day, retains

on the hill above the port of Liverpool

Coming from a region where history is long and the land little, to this where written history is short and the expanse of land incomparably great one realises how relative is size And in regard to the event of to day the largeness of this country rises in my thought not as a matter of mileage, but that with you, more than with us in the old country, the size of to morrow is vaster than the size of to-day Each step of progress here more than with us, has to be measured by its ample consequences in a more rapidly widening horizon of the morrow These new laboratories have a field already demanding them and a still larger lies before them in an immediate and historic future

PURSUIT OF SCIENCE A CIVIC DUTY

Biology is the study of life in regard especially to growth and to organisation Every medical man is a biologist and as a biologist it may be but natural if I regard to day's event from a biological standpoint and the community as an organism and the university as a living organ essential to the healthy life of the community Science—especially medical science—is growing in importance to the community We must have organisation in science as in industry This University to day makes provision of first rate importance for the organisation of medical and allied sciences in the region which centres here Capacity to rear and to support men constitutes the extent

individuals, requires the vigilance of guiding hands Growth for it to take its course rightly towards perfection requires that provision for the security and expansion of the liberal arts and sciences forerun rather than halt behind the actual requirement of the hour Not only for their direct utilitarian service They form a whetstone for man s most universal tool —his intellect Also a discipline for character in the pursuit of truth for its own sake Scientific truth, when found, has often proved unpalatable to man—as when it dethroned him from his fancied seat at the centre of the whole perceptible universe, a universe he had imagined simply subservient to his needs, or again, as when it taught him that instead of being a creature altogether apart from brute creation there are flesh and blood bonds between himself and them Regardless of its cost to his cherished fancies man strives for scientific truth And, as the old Greek said, this purpose puts him further from the brutes and nearer to the gods *In nurturing science I would urge* that a community cultivates more than mere utility And even with regard to mere utility, as the fields of knowledge fall ripe under the ceaseless husbandry of the world's thought, those who would join in the great reaping and not only glean where others reaped before them must cultivate for themselves To do this requires more than the devotion of individuals It requires the intelligent cooperation of whole groups of individuals Organised scientific inquiry becomes in advanced countries a conscious aim of *the community as a community*

THE VARIOUS WORKERS

That society may draw due benefit from wells of natural knowledge three kinds of workers have to stand side by side First the investigator who, pursuing truth, extends discovery with little or no reference to practical ends He constitutes the fountain head of the knowledge that is for distribution Other hands may reap the harvest but his set and rear the seed After the investigator comes the teacher To him it belongs to diffuse the knowledge won This honourable and difficult task receives its best reward in seeing the small spiritual beginnings of a pupil widen into the spiritual beginnings of a master Thirdly, there is the applier of natural knowledge His part consists in making scientific knowledge directly serve practical needs It is this work which to the popular idea often represents the whole of science or all of it that is commonly termed "useful The practical results of this work are often astounding to those ignorant of the steps by which they have been reached The greatest of these steps however, is usually the first one, made in the laboratory of the investigator These three co workers are co-equal in the priesthood Science and the applications of science are one growth, united together even as the fruit and the tree The proper hearthstone round which the community should group these labourers, labouring for a common end is the university There the sacred flame of learning is fed from many sides by many hands

THE BIOLOGIST AS CITIZEN

It is sometimes said that pursuit of science renders a man deaf to the appeals of practical life—that it tends to withdraw him from the everyday interests of the people That I do not believe of any science certainly not of biology and the medical sciences Why, from their very outset these subjects draw the mind towards study of an organisation the most complex and the most perfect it can examine The ancient simile that our old school classic Livy, drew between the human body and the body politic the State, has not lost but won significance as the centuries have run The *achievement* of the microscope has been the discovery that living things whether plant or animal—all living things of more than minutest size—are commonwealths of individually living units These cells as they are called, are living stones that build the house of life In that house each stone is a self centred individually living microcosm individually born, breathing for itself feeding itself, consuming its own substance in its living, and capable of, and destined for, an individual death Each cell lives by exchanging material with the world surrounding it In other words, its bulk depends on its surface Hence surface increasing as the square and volume as the cube, cell size is circumscribed by tiny limits—microscopic limits. Had the dependence been greater than it is and the average size of the cell less and too small for resolution and discovery by the microscopes of 70 years ago it is hard to imagine where biology would stand to day For two generations every biologist has been accustomed to think in terms of the cell theory Every shred of the body he knows as an intricate interlacement, embodying coöperation and mutual support of associate thousands of individually existent cells Division of labour has gone on and with it differentiation of structure while this group of cells combines with its own inner life some special function subservient to the needs of the great commonwealth as a whole, another group is specialised for another duty again subservient to the general needs. Each organism, with all its solidarity, each one of ourselves here, is built up of living myriads. Each such organism consisted at the outset but of a single cell and from that in his life's growth have arisen the countless myriads composing him to-day. The blood relationship is close between all the cells of each one individual body. The cells of our nerves, of our muscles, of our lime-hardened bones are all blood relations through one common ancestor. Yet so far has specialisation of these unit lives gone on, so far does function reflect itself in microscopic form, that there is greater likeness between my nerve cells and the nerve cells of a fish than between my nerve cells and my own muscle cells, despite the blood relationship between these latter. And in the commonwealth of cells that constitute each one of us goes forward day long, night long, as in the body politic, the birth of new units to replace the ones outworn, the subordination of many individual purposes to one, the sacrifice and destruction of the individual life for the benefit of the many.

Trained in study of such an organism surely the biologist and the medical man will be the last to underrate the importance of organisation to the community for the common weal. Therefore I am rejoiced, but I am not surprised, that it is your Faculty of Medicine which to day in its public-spiritedness erects and instals these fine laboratories, this potent addition to the organisation of your community for its activities in medicine and biological science. I would also, as a friend among you, offer you my congratulations on the consolidation of your two schools of medicine. Union means not only greater strength but the more effective application of that strength.

TWO ASPECTS TO MEDICINE.

I need not extol medicine to this assembly. Many of her votaries are here; I venture to count myself as one. But to-day the relation toward her of education is a matter on which our minds are naturally set. Am I wrong if in regard to this it rises saliently to me that from the educational standpoint medicine, like Janus of old, in a good sense, bears a double face? On the one hand, she is an empiric. She has learned to cure by what the comparative psychologist calls the "method of trial and error"—conquests over sickness acquired purely as the result of experience without help either from *a priori* or from inductive reasoning. And great and glorious is the rôle of her achievement on these lines. Of her humanitarian triumphs probably still—certainly until a generation ago—the greater share is assignable to this part. The use of quinine in malaria, the curative effects of the iodides and various metals, the discovery of chloroform and ether as anæsthetics—these and the names of a long line of famous physicians from the Renaissance down to some as justly famous as the past and with us now to day suffice to certify the inestimable gifts that medicine as empiric has given to suffering mankind. This face of medicine may well wear a garland.

In her other aspect medicine is not an empiric but a scientist. Who will refute me if I assert that medicine is as well an art as a science? Somewhere it is said that woman is the last thing man will ever civilise. So the scientific aspect, the male face of two-visaged medicine, thinks of that female face, the empiric, with whom his lot is linked. He feels sometimes that his other half is the last thing science will ever render wholly rational. By dint of patient toil he improves her practice, showing her a reason now and then. No sooner that than she is off on a fresh flight into the inexplicable and he must cudgel his brains anew to find her a fresh logical position.

That feminine, ever-youthful trait in medicine has to the student an undying charm. But on the whole the countenance of medicine has of recent years for the student become masculinely severe. The masculine head of medicine has indeed become the larger. Hydrocephalic even in appearance, yet is it filled not with water but with reasoned facts. All this development proceeds in the main from certain data acquired in the century just passed. The chemist, in discovering that all the million-sided chemical diversity of the perceptible universe is composed from a few—some 70—substances, therefore called elemental, discovered also that living matter instead of containing elements different from and subtler than those of the dead world, consists of just a few of the commonest of those same ones. Further, the doctrine of the indestructibility of matter was demonstrated in a new form—namely, as the indestructibility of energy, and the convertibility of any one form of energy into other forms. Thus dead and living matter have become united as subject material for study. It became really possible to consider the living body as a chemical and physical machine, a machine to which the laws of chemistry and physics can be applied. But this scientific progress in medicine, fruitful of benefit to the community, lays on the community a burden of obligation.

HISTORICAL SKETCH.

The empirical part of medicine is at once the most easy and the most difficult thing to teach. The preparation for learning it requires but little training in other subjects. Its facts lean on nothing but themselves.

With the scientific part of medicine it is different. That is based upon initiatory studies. Medicine, historically traced, we find first drawing help from the simplest and nearest at hand of these adjuvant studies. First she bent to the study of the gross form of the parts and organs of the body. The gross form of these is significant chiefly where they are machinery for application of mechanical powers. The greater part of the corporeal machinery is, however, not destined for such work, but has its purpose in processes, chemical, thermal, and electrical, to which—marvellous appendage—mentality is adjunct. Medicine in the course of the seventeenth and eighteenth centuries sucked dry for the most part what the study of the gross form of the body's parts could yield her. She then turned to the study of microscopic form—examined what Bichat first named the *tissues*, the fabric of the body. In so doing she came upon a great generalisation, the cell doctrine, discovering an essential and visible similarity of microscopic structure in all that has life, differentiating it from all which has not life.

But even before the advent of the cell theory medicine had begun to ask of chemistry what it could give her. With the discovery of oxygen and of the nature of combustion the links between biology and chemistry began to be tightly drawn. The young Oxford physician, Mayow, had performed the fundamental experiments on respiration and had discovered oxygen more than a century before Priestley and Lavoisier. But the time was not ripe until the stupendous work of Lavoisier had founded modern chemistry. The cell theory was from the first not only morphological but physiological. It meant, for the application of chemistry to biology, that the chemistry of the body or of one of its organs was a chemistry resultant from a thousand tiny living furnaces, individual seats of oxidation, deoxidation, polymerisation, hydrolysis, and what not. Not only that, but the living laboratory of the cell itself manufactures even the medium in which the cells themselves exist: the saps and juices of the body. And we are beginning to know, thanks to pathology, that every species of animal produces an internal medium specific to itself. Further, your distinguished physiologist here, Professor Macallum, who has done so much to reveal the distribution of the chemical elements within the cell, tells us that the internal medium which the cells of even the highest animal forms produce, as appropriate for themselves, still approximates in its salts to the water of the ancient geologic seas in which their ancestry arose and still reveals in fact the composition of that ancient ocean. In that respect these living cells, with all their flux of change, have been more durable and constant even than ocean itself. The contrast brings home to us a deep distinction between dead matter and living—the latter a moving equilibrium, gaining stability from the very motion of itself.

The bonds between medicine and chemistry with Schwann and Pasteur were drawn still tighter by their discoveries concerning those subtle influences named "ferments." Pathology, the study of these processes of the body in disease, even more than physiology as yet has drawn help from this part of modern chemistry. If the processes of health are in fact the resultant of the due coöperation of ten million little foci of healthy chemical action in the body, the processes of disease are similarly divisible and have to be traced to the unhealthiness of certain of these minute centres of activity. How extreme is the importance of chemistry to modern medicine no single statement can perhaps emphasise so well as this—that is, I believe, acknowledged on all hands—that in virtue of his chemistry a chemist, Louis Pasteur, during the latter half of last century was able to do more to alleviate the diseases of mankind and animals than any single physician of his time. To the physicist also medicine has made appeal. From him she has got understanding of the body's heat, the basis of the knowledge of fever; she has learned the intricacies of the mechanism of the eye and refined methods of examining that organ and of remedying many of its defects , the laws that govern the circulation of the blood, and the subtlest means of detecting the forces liberated in the working of the nervous system In some cases as sciences grow, their discoveries seem to sunder them the further one from another In my belief that merely shows they are at the outset of their careers To day we find physics and chemistry converging and conjoining within a field of physical chemistry It early became convenient to have a specific name for living material wherever found The name given was ' protoplasm ' It might have been better to call it ' x " or " y " so far was it in many respects an unknown quantity Instead of looking forward to this material as a chemical entity we incline now to regard it rather as a *field for chemical action satisfying certain particular conditions* Probably discoveries regarding these conditions will fall to the physical chemist, perhaps in a future very near at hand Probably such discoveries will be among the most valuable that medicine has yet received from any source

MEDICAL EDUCATION

I have said enough to remind us how interlocked with science medicine has become She is applying sciences to her own problems and they form a vast capital fund from which she can draw wealth To give instruction in this part of medicine, to turn out men trained in it is now one of the duties of a medical school The earnest student has a right to expect such training from his *alma mater* But for it the requirements are importantly different from those that suffice as an introduction to empiric medicine In the first place as Pasteur said, we cannot have the fruit without the tree For scientific medicine the student must perforce be thoroughly trained in his sciences before he can really grasp instruction or truly profit from his medical *teaching One of the aims* of his instruction in empirical medicine is to teach him to observe for himself So in his instruction in scientific medicine one of its aims is to enable him to apply science for himself How small a fraction of all the realities of medical practice can be met in the few years of preparation of the student in the clinic as he passes through it in his school career His teacher knows that well and uses the cases there as types whereby the principles of medicine can be fixed as a beginning The rest must be accomplished by the man himself as his life's work The more necessary that the man go forth from his school equipped, not only with the present applications of science to disease but so possessed of root principles of the sciences adjunct to medicine that he may grasp and intelligently use the further developments of scientific medicine after he is weaned from his instructors and the school That is a way to obtain enlightened progress in professional practice What truer safeguard can a man have, alone it may be, and

sciences along whose lines the discoveries of medicine must develop ?

BURDEN ON TEACHERS

Therefore it is that the burden of obligation falls heavy nowadays upon the teaching resources of every faculty of medicine worthy of the name There is, in the first place the burden of increased intellectual labour For both the learner and teacher is this true To seize the proffered assistance of these great and complex sciences is not always easy These studies are more difficult than those that were needed once and they take longer to acquire The mere instrumentarium of modern chemistry and physics as applied to medicine, and of physiology and pathology and bacteriology and of hygiene of itself suffices to bring conviction of the increased difficulty and longer training due for these studies now preparatory to medicine Further, these initiatory studies have become vastly more costly than was all that formerly was required Experts have to be found who can devote themselves heart and soul and undividedly to their particular subject Laboratories have to be erected and equipped and on a scale that makes them a distinct feature of the modern world Those that we see now here are models of their kind , wise foresight has planned them , public spirited enterprise has constructed them accordant with that plan Nor does the achievement end with their erection The laboratories and their equipment are but the *factory and the plant , both fail in their purpose if they halt* for sustenance And beyond that the likeness does not go The factory, once started, if it be wanted, can expect to pay, to support itself Not so the laboratory The laboratory is both a school of instruction and a school of thought. Well, no higher instruction can be expected unaided to pay the expenses it involves , it can only do so at the expense of those who come to learn and that is to put its teaching beyond the reach of all but the wealthier few And the instruction is costly for it has to be practical

Another source of expense is that the laboratory has not only to distribute knowledge but to manufacture it The duties of a university do not begin and end with the disciplinary and didactic Besides schools of instruction they must be schools of thought To be this latter the laboratory must pursue research Even for the welfare of the class teaching this is essential Instructive lectures may be given *by men of ability the whole of whose knowledge is second* hand but it is doubtful whether the real life of science can be fully felt and communicated by one who has not himself learnt by direct inquiry from nature Nothing more augments the teacher's power of impressive and incisive teaching of a subject than to have faced problems in it himself as an original inquirer And after rudiments have been once fairly acquired there is for good students no training equal to that given by following even a small research under an experienced leader

SCHOOL OF THOUGHT

So, truly, does the laboratory become a school of thought Your laboratories are arranged with admirable provision for *research The student should enter on his study of a natural* science through the portal of its fundamental experiments The attitude his mind thus takes is the true one—the only true one—for further insight into the subject Too often humanistic studies at school have tended to kill the natural philosopher within the child—to destroy that innate curiosity for facts the healthy heritage of childhood He leaves school a little bookman Even as to the phenomena of nature he has been insensibly led to ask for statements upon authority rather than to turn his own senses and observation to the phenomena themselves To learn a science or to acquire an art resting upon sciences the first thing to do is to look at the fundamental facts for ourselves Our great teachers of medicine teach upon this plan They teach where they learned not in the library, but at the bedside of the sick In laboratories such as those raised here for pathology and physiology students can learn these sciences as medicine is learned in the hospital ward by direct inquiry into nature The teachers you give them are men who have won widely recognised distinction as themselves direct inquirers into *nature* Worthy students will appreciate this double boon their *alma mater* gives them—the means of learning at first hand those secrets of nature which lie at the root of their craft's skill and to learn them under guidance by men who excel in unravelling such secrets

ENGLISH ACTION

Only by enabling men to continue their learning after their teaching is over can we secure the greatest advantage any educational system can afford Your laboratories here will encourage post graduate work We look with keen interest to the researches that will flow from them No subjects offer finer fields for research than do the progressive studies, physiology pathology and hygiene, to which your new University buildings are *consecrated And of the functions* of a laboratory, research is not the least costly We in the old country find that Our central Government has done little to support research Our nation proud of its success in things practical, has been prone to despise the abstract and the theoretical We do so foolishly , we do so at our peril Behind all practical application there is a region of intellectual action to which though our practical men have contributed little they owe the whole of their supplies Theory if a goose is the goose of the fairy tale that lays the golden eggs No more such eggs if once you let her die To speak of theoretical knowledge slightingly is for the lips of the fool. The value of abstract research to a country is becoming more widely acknowledged among us than it was Sir John Brunner said the other day at Liverpool that there was no better investment for a business man than the encouragement of scientific research and that every penny of the wealth he possesses has come from the application of science to commerce and to manufacture And we find that munificent citizens have and do come forward among us and *meet* by their individual gifts the pressing needs in this respect of our community at large

NEW ERA DAWNING.

But we welcome a new era dawning on us. Liverpool, Birmingham, Sheffield, and other great centres begin to regard the local university as an institution entitled to support from the public means—for instance, by subsidy from public rates. Such subsidies can be used also for studies which do not come within allotment from the smaller subsidy from the central Government—medicine, for instance. Proud of the young universities—to which yours of Toronto is a time-honoured veteran—communities and local governments are encouraging research within our universities. They do not expect such research to be able to pay its own way, but they recognise that indirectly it does pay the community that gives it a home. They feel it a duty which they owe themselves. Is not the university a part of their own life, and is not research a part of the university's life blood? They feel it a right due to their own higher selves. It stimulates progress. Supported by the large-handed sympathy of the community and the local government, it means quicker advance, both material and mental, it means invention, and it means medical discovery. And *qui facit per alium facit per se* is a motto worthy of a State.

USES OF LABORATORIES.

What, then, are finally the uses of these laboratories now opened by your University? They will assist in training men for various honourable callings, especially for that most ancient one of medicine. They will assist, no doubt, also to render life by practical applications of science superficially still more different from what it was only a short generation ago. They will assist to bring home and to distribute to your community treasures of knowledge from all the quarters of the globe. They will themselves assist—and it is a thought dear to a high-spirited people—to add to the sum total of the treasures of knowledge of the whole human race. "Noblesse oblige" appeals to chivalrous nations as well as to chivalrous individuals.

But their highest office seems to me, perhaps, not even these high ones but a more difficult still. Genius cannot by any community, however wealthy and powerful, be made to order. In biblical language it is the gift of God. All a community can do toward obtaining it, be our riches and willingness a thousandfold what they are, is to ensure the rare and glorious plant a meed of freedom, light, and warmth for blossoming upon our soil. Who can doubt that in this population here genius exists—not sown, it is true, broadcast, for nowhere is it thus—yet existent, scattered up and down? This it is for the community to foster, to discover. By help of these finely built and complete laboratories this much in one direction can be done. The problem to which a wise country turns is the discovery less of things than of men. By these laboratories, adequately supported, your community can create opportunity for the exercise of powers which come from sources within itself but are utterly beyond its power to produce at will. Their loftiest function is creation of this opportunity. For that aim the studies in them must be followed with no single narrow technical purpose but must be wide of scope and full of access to every rank of student. So shall these laboratories prove a corner-stone for the upbuilding of a temple of knowledge and a touchstone for the best ore of intellect within the bounds of this great land.

CHARING CROSS HOSPITAL. — On Thursday, Dec. 10th, a dance will take place at the Whitehall Rooms of the Hôtel Métropole, under the patronage of Princess Louise, the Duchess of Argyll, President of the Hospital, the Duchess of Devonshire, the Duchess of Sutherland, the Duchess of Marlborough, and the Duchess of Portland, with the object of raising a fund for the renewal of the floors of the old wards of Charing Cross Hospital. The music will be supplied by the string band of the Royal Engineers.

MOUNT VERNON HOSPITAL FOR CONSUMPTION.—On Oct. 27th Lord Zetland, President of the hospital, formally opened the newly erected east wing. This hospital, which is situated on Hampstead Heath, contains 145 beds. The present extension has been erected at a cost of £16 000 and the cost of the whole building amounts to £43,500, or £300 a bed. Of the 45 beds provided in the new wing the committee does not feel justified in opening more than 25 at present as it still needs a sum of £10,000 to defray the cost of the extension, furnishing, and other charges.

The Bradshaw Lecture

ENTITLED

SOME OBSERVATIONS ON TUBERCULOSIS OF THE NERVOUS SYSTEM.

Delivered at the Royal College of Physicians of London on Nov. 5th, 1903,

BY E. F. TREVELYAN, M.D., B.SC., F.R.C.P. LOND.,

HONORARY ASSISTANT PHYSICIAN TO THE LEEDS GENERAL INFIRMARY; PHYSICIAN TO THE LEEDS SANATORIUM FOR CONSUMPTIVES; PROFESSOR OF PATHOLOGY, YORKSHIRE COLLEGE, LEEDS.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to acknowledge the honour done to me in asking me to give this lecture and to express the hope that I may prove worthy of it. I propose to address my remarks (1) to the forms which the tuberculous infection may assume in the nervous system; (2) to the mode of infection of the brain and meninges; (3) to some points in diagnosis connected with spinal puncture; and (4) to the possibility of recovery. I have to express my obligations to my colleagues on the staff of the Leeds General Infirmary for permission to use the records of 114 fatal cases which have occurred during the past 20 years in that institution. I must also thank Dr. Ursula Chaplin for much able help in laboratory work. To Professor S. Delépine and Professor G. Sims Woodhead, Mr. G. Dean of the Jenner Institute, and Dr. Steegmann of the Royal Commission on Tuberculosis I am indebted for some virulent cultures of the tubercle bacillus and to the last named also for valuable references.

FORMS WHICH THE TUBERCULOUS INFECTION MAY ASSUME IN THE NERVOUS SYSTEM.

The various forms of tuberculosis of the nervous system consist of tuberculosis of the dura mater, tuberculous meningitis in its more general and limited forms, tuberculous masses in the brain and cord, and a possible miliary tuberculosis of the brain itself. An old question mentioned by Rilliet and Barthez[1] many years ago has been much discussed lately as to whether it is possible to have a tuberculous meningitis without the presence of tubercles, or at any rate with only a minimal tubercle formation. Such an affection has been compared to certain benign tuberculous affections of joints and serous membranes and the name of tuberculous meningopathy has been suggested to distinguish it from the ordinary fatal form of tuberculous meningitis. Poncet,[2] Patel,[3] Sepet,[4] and Galliard[5] are the chief exponents of this view and the subject has been well summarised by Bouclier[6] in a recent Lyons thesis. Among the 114 fatal cases at the Leeds General Infirmary there are 14 in which thickening or exudation is noted at the base of the brain without visible tubercles. Cerebral symptoms were present before death in 12 of these cases and abundant tuberculous lesions elsewhere in the body in all. I think it is fair to conclude that tubercle formation was at its minimum or even absent, at any rate in some of these cases, and that the changes noted were a manifestation of the tuberculous infection and were responsible for the symptoms. It has been suggested that the poisons of the tubercle bacillus may cause this more exudative or serous form of meningitis. Armand Delille has separated a poison which produced in his experiments productive tissue changes. On the other hand, the poisons of the tubercle bacilli injected intrameningeally may cause rapid death, as in Martin and Vandreuver's experiments.[7] Sicard[8] states that the tubercle bacillus and *its toxin* can produce exudation and granulations. In three instances of intrameningeal injection of measured quantities of tuberculin I found no local effects but progressive wasting ending in one guinea-pig in death. More information is obviously wanted about this benign form of tuberculous [illegible]

[illegible] us meningitis the [illegible] ch cases have been recorded by Saenger[9] and in one case in my list the lesion was limited to one Sylvian fissure. But the limited meningitis described by French authorities (Chantemesse,[10] Combe,[11] Monnier,[12] and others) consists of a great thickening with tubercle formation over a limited portion usually of the motor cortex. It is said to occur in phthisis and its symptoms, as Combe points out, differ from those of ordinary tuberculous meningitis. There are nine cases in my series in which such localised thickening over a limited area of the cortex was noted. The most marked case was in a boy, aged seven years. The plaque occurred over Broca's convolution and difficulty in speech was noted during life. In this case there were miliary tubercles in the lung and in three other cases phthisis. This localised lesion may be produced experimentally (Sicard) and I have myself seen an instance of it.

Tuberculous masses in the brain are not infrequent. They were present in 33 of the 114 cases. In 15 they appeared to be recent and but little antecedent to the existing meningitis. In only 17 of the 33 cases were they multiple, a smaller proportion than usual. The largest number present in one case was four. In Middleton's case[13] there were 20, in Homen's case 12,[14] in West's case 12,[15] and in Henoch's case 12.[16] In size they vary from that of a millet seed to that of an orange and larger. They are mostly well defined and shell out with ease. Minute tubercles are often visible in the bed and on their surface, making recognition easy. They are often surrounded by an area of vascular engorgement but as a rule there is no definite capsule. They vary in consistency and when laid open display a yellowish and caseating centre and a peripheral growing zone made up of recent tuberculous tissue. Tubercle bacilli may or may not be found in this peripheral zone. As a rule, these masses show little tendency to break down and still less to calcify. They develop mostly in the grey matter and when they are situated more deeply they are often in relation with a process of the pia mater. Their favourite sites are the cerebellum, the pons, the crura, the cortex, and the central ganglia. Except in the pons, the medulla, and the cord, where they are usually surrounded by nervous tissue, they most often project on to the surface. The infection of the cerebro-spinal fluid is thus easily brought about as Ziegler[17] points out. Tuberculous tumours, indeed, sometimes give rise to no symptoms until this infection occurs. In 23 of my 33 cases there was present a tuberculous meningitis. In one of the cases there was a loose tuberculous tumour in the fourth ventricle. I have seen a section prepared from it by our pathological curator, Mr. J. A. Cairns Forsyth, and although there are no giant cells in the peripheral zone and no tubercle bacilli have been found, I do not doubt its nature. There were other tuberculous lesions in the body. Tuberculous tumours of the spinal cord are not common. Dr A. G Barrs had this drawing made of one and I have brought another specimen. It came from a child, aged three years, and there were other similar masses in the brain. Auiel and Rabot,[18] Müller,[19] Luce,[20] Gourand,[21] and Hunter[22] have recently related interesting cases of these tumours of the spinal cord.

In one of my cases an abscess possibly tuberculous was found in the pons along with tuberculous masses in the brain. Delafield and Prudden[23] state that these tuberculous masses may break down into abscesses There is at present a beautiful specimen on view in St. George's Hospital museum, which shows multiple tuberculous masses breaking down into abscesses containing tubercle bacilli. The relatively rare tuberculous tumours of the dura mater are nearly invariably multiple and grow from its inner vascular surface in the posterior fossa or from the falx cerebelli. One of the two specimens from our museum came from a child, aged six years, with tuberculous cavities in the lungs, caseous bronchial and mesenteric glands, and intestinal ulceration. Miliary tubercles of the dura mater were noted twice, once by Dr. T. Wardrop Griffith, to whom I am indebted for many valuable comments upon the necropsies made by him.

MODE OF INFECTION OF THE BRAIN AND MENINGES.

It is admitted that a complete examination almost invariably reveals an older tuberculous focus somewhere in the body. In only six of my cases was no such focus found and here the notes are incomplete. Under congenital tuberculosis I need only refer to Demme's well-known and unique case[24] of a tuberculous cerebellar tumour in an infant, aged 23 days. If our knowledge of the infection of the meninges and brain were at all complete, which is by no means the case, we should know where the infecting focus is, what brings about the mobilisation of the tubercle bacillus from it, what channels the bacillus travels by, and what determines its settling down in any given area in the brain. The actual infecting focus may exceptionally be small and easily overlooked and it is obvious that the oldest lesion is not necessarily the infecting one.

A direct infection through the nose is believed to be possible, as in Demme's case quoted by Cornet.[25] A spread from tuberculous disease of the ear may take place; it is not quite direct because the ear would appear to be infected through the lymphoid tissue of the nasopharynx. Some recent experiments and observations tend, however, to show that the tonsils and the lymphoid tissue in the nasopharynx do not contain tubercle bacilli (at least virulent bacilli) as often as has been urged (Macfadyen and Macconkey[26] and Ito[27]). Grimmer,[28] who has worked at the subject, puts down tuberculosis as the cause of middle-ear disease in from 65 to 70 per cent. in children under five years and 16 per cent. above that age. There was obvious ear disease in ten of my 114 cases which were mostly admitted under the care of Mr. H. Secker Walker and Mr. A. L. Whitehead. Although the ear disease was not proved to be tuberculous it is interesting to note that in seven of these cases there was another old possibly infecting focus in the body and in another two the state of the glands is not noted. Experimentally I believe that it is very difficult to infect the brain and meninges through the accessory cavities. Again, in spinal caries I take it that a general tuberculous meningitis is of infrequent occurrence. There are only four such cases in my series. In two the organs are said to be normal, in one the mesenteric glands are said to be enlarged, and in the other the glands are not noted at all. Miliary tubercles on the inner surface of the dura mater were noted in one case. In Dr. T. Churton's case of a large tuberculous tumour in the frontal lobes the spread from the bone to the dura mater and the brain seemed obvious, unlike a rather similar case recorded by Curtis and Booth[29] where the spread was said to be from within. Poli[30] suggests that the dura mater forms an important barrier against the spread from a neighbouring focus. In a single experiment devised to test this view I quite failed to confirm it.

The lungs were normal in 28 cases. It has been proved (as stated by Boinet[31]) that tubercle bacilli may pass through the lungs without leaving an obvious recognisable lesion. A miliary tuberculosis of the lungs was noted in 54 cases. 18 cases presented the lesions of phthisis, together with a miliary lesion in nine of them. Phthisis is said to be the most common cause of tuberculous meningitis in the adult. Personally I have had very little experience of this complication in obvious phthisis, although during the past four years I have had the opportunity of watching the course of phthisis in a considerable number of cases in connexion with the Leeds Tuberculosis Association. One case which I saw with Mr. B Wainman I have reason to remember as I failed to assign the quite early vomiting to its proper cause. Among the cases of phthisis there was a child, aged six years, with one large cavity and several small ones. There are four other cases in children with recent cavitation which are not classed as phthisis.

[illegible]

Joints and bones were affected in 23 out of the 114 cases—viz., the hip in 13, the ankle in three, the knee, the elbow, and the wrist each in one case, and in four cases two joints were involved. The hip disease was old in two cases. Recently Courtin and Lourde[32] have described tuberculous meningitis in quite early hip disease. The small amount of tuberculosis noticed in the body in some of these joint cases was striking. The bones affected were the spinal column in four cases and the frontal bone and the ribs each in one case. In four cases the kidneys were the seat of extensive tuberculous disease. It was associated in one case with pulmonary and laryngeal phthisis, in another with hip disease, and in a third with ear disease. The generative organs, no doubt not always examined, are noted as diseased in two cases, once in a man with a tuberculous testis and vas deferens and once in a woman with tuberculous Fallopian tube disease and tuberculous peritonitis. Simmond's statistics[33] show an extraordinarily high percentage. Thus in 60 cases of tuberculous meningitis one-third had genital tuberculosis. 35 of the 60 were men and here one-half were similarly affected. Ordinary tuberculous peritonitis was noted in eight cases and intestinal ulceration, mostly recent, in 28 cases. In another case there was extensive tuberculous ulceration of the colon and the rectum. Widenmann[34] reported a curious case of tuberculous meningitis in a man with primary ulceration of the intestine. In two of my cases there was an abscess about the vermiform appendix.

The relation of the lymphatic glands to tuberculous meningitis is of the first importance but unfortunately my records are distinctly incomplete in this respect. The lymphatic system constitutes a most important defence, especially in the child, against a general tuberculous infection. Manfredi and Fresco have been able to demonstrate even in so susceptible an animal as the guinea-pig the important rôle which the lymphatic glands play. There is a difficulty in connexion with these glands—viz., that they may contain virulent tubercle bacilli and yet appear as healthy to the naked eye. The glands which stand in the most direct relation to tuberculous meningitis are the mediastinal. Haushalter and Fruhinsholz[35] have recently found old and caseating lesions in the pretracheo-bronchial glands in 63 out of 67 cases of tuberculous meningitis. It is a particularly striking fact that in as many as 40 cases (35 with miliary tuberculosis) no old focus was present other than the adenopathy. This close relationship can only be connected with the all-important fact that the lungs constitute the port of entry of the tubercle bacillus in the large majority of these cases. Carrière[36] believes that the mesenteric glands may be the infecting focus in a goodly number of cases of tuberculous meningitis. It should be remembered that the infection of the mesenteric glands in a retrograde fashion from the mediastinal glands is obviously an anatomical possibility. We are obliged to appeal to this retrograde infection to explain some features in the spread of experimental tuberculosis. This mode of infection is more likely to be effective if there is any pressure upon the thoracic duct by enlarged and caseating mediastinal glands.

More puzzling still than some features connected with the infecting focus is the mobilisation of the tubercle bacillus from it. It has been suggested that tuberculin may bring about this effect. Rutimeyer's case[37] of phthisis in which tuberculous meningitis appeared at the close of a course of tuberculin treatment is very suggestive. I am aware that Cornet in his admirable work on tuberculosis will have none of this explanation. Simmonds[38] has seen cases of genital tuberculosis in which tuberculous meningitis ensued within from a few weeks to months after marriage. The occurrence of tuberculous meningitis shortly after an operation is a still more important matter. I have found eight cases of this class among the 114 cases. The interval between the operation and the meningeal infection forcibly reminds one of the incubation period in experimental tuberculosis. This interval has varied from one week to six or seven weeks; at least one case must be excluded as the interval is too short. The operations were upon the cervical glands, the ankle and the hip joints, also a laparotomy, &c. An absolutely satisfactory explanation is not forthcoming. Some have thought that tubercle bacilli have been liberated in the field of operation and have then gained access into the blood current. No doubt this view should receive practical attention. In the parallel case where an early phthisis blazes out after an operation into a fatal activity, of which I have recently seen two cases, one with Dr. Gordon Sharp, an explanation appears to me to be at hand. It may be attributed to an actual inhalation infection of hitherto sound parts of the lung brought about by the deep inspirations caused by the anæsthetic. Rhodonacki[39] has also recently published two cases of a fatal aggravation of the pulmonary lesion after operation. It has been suggested in cases of tuberculous meningitis following rapidly upon injury, as in a recent case by Mollard (quoted by Bouclier[40]), that the actual mechanical concussion may have led to escape of tubercle bacilli from the infecting focus but this explanation is not by any means convincing. There appears to be no satisfactory explanation of the occurrence of the disease at an interval after measles, whooping-cough, &c.

The route by which the bacilli travel from the infecting focus to the meninges or brain is far from satisfactorily worked out. It is either by the blood or the lymphatics. A striking fact in connexion with tuberculous meningitis is the marked alteration in the blood-vessels. In one case under the care of Dr. Barrs the Sylvian artery was blocked. Similar lesions have been recorded by several observers. In Cruchet's case[41] of at least a temporary recovery from tuberculous meningitis there were abundant old tubercles about the posterior cerebral and basilar arteries, the latter being almost occluded. In laying open the branches of the Sylvian arteries in one case I could see tubercles in the vessel walls. Sicard[42] has shown experimentally that the meninges may be infected, though with some difficulty, by injecting tubercle bacilli into the carotid artery; a pulmonary tuberculosis, however, is the common result unless the jugular veins are tied. Cornil, Bezançon, and Griffon[43] have studied the changes in the brain after injecting tubercle bacilli into the carotid artery of rabbits. No bacilli were found in the arterioles but they had multiplied in the perivascular sheaths which were filled with large swollen cells. The process illustrates according to the authors the development of tubercle at the expense of the lymphatic sheath. On the other hand, Sicard states as the result of his investigations that it is impossible to infect the meninges through the lymphatic system. These changes in the vessels, along with the experimental evidence, make it appear almost certain that the tubercle bacilli arrive by way of the blood stream. If they arrive in numbers they produce an ordinary general tuberculous meningitis, if few in numbers or perhaps attenuated they give rise to tuberculous tumours or even a meningitis *en plaque*—viz., an expression of a less virulent infection. Occasionally, and then I think only in the pons, the tuberculous tumour may look as if it had been formed, or was forming, by the coalescence of several foci of infection. Broca and Souques[44] endeavour to explain the frequency of tuberculous tumours in the paracentral lobule (and Dr. Churton[45] some years ago recorded a well-marked case of the kind) by the rich vascular supply and the slowing down of the blood current here. It is curious that the lesions of the ordinary tuberculous meningitis should usually focus themselves chiefly about the middle cerebral artery and its branches, whereas tuberculous tumours are more frequently found in the distribution of the basilar and posterior cerebral arteries.

EXAMINATION OF THE SPINAL FLUID.

Undoubtedly a most important addition to our resources in diagnosis consists in the examination of the cerebro-spinal fluid obtained by Quincke's spinal puncture. During this year I have examined the fluid from five cases of tuberculous meningitis. In one case, that of a boy, aged eight years, in the infirmary, whom I saw by the kindness of Dr. O. M. Chadwick, there was a pleural effusion present when the cerebral symptoms supervened. Ten cubic centimetres of clear fluid were drawn off. It contained a faint cloud of albumin and in the deposit lymphocytes alone were found and no tubercle bacilli. A small quantity of fluid, less than two cubic centimetres, injected subcutaneously tuberculised a guinea-pig. Another case, seen with Mr. H. J. Roper of Leeds, occurred in a boy, aged seven years, who had just passed through an attack of scarlet fever. The urine contained albumin and the vomiting in the very early days suggested a uræmic origin for the symptoms. On the second occasion on which I saw him there was a slight facial paralysis and the nature of the case seemed obvious. The clear spinal fluid contained very *little* albumin; the deposit showed many polymorphonuclear cells but no tubercle bacilli were found. The inoculation test gave a positive result. In a third case, that of a girl, aged four years, whom Mr. Norman Porritt of Huddersfield asked me to see, lymphocytes were present but *no tubercle bacilli were found in the fluid. The inoculation* test also gave a positive result. In another infirmary case the fluid was obtained after death. Albumin was present and lymphocytes were found in the deposit but no tubercle bacilli. A quite recent case occurred in a lad, aged 16 years, whom I saw with Mr. D. McCann and who was transferred to the infirmary under my care. He was punctured at my request by Mr. G. W. Watson, our resident medical officer, on three separate occasions and 15, 35, and 13 cubic centimetres respectively of spinal fluid were drawn off. On the second occasion the pressure (four and a half inches in terms of the fluid) was estimated by Krönig's apparatus. Death occurred about the seventeenth day. There was miliary tuberculosis of the meninges, the peritoneum, and the upper lobe of the left lung. The bronchial glands were caseating and the mesenteric glands were enlarged. *The spinal fluid was clear with a few small flocculi* in it on two occasions and on the third it was more straw-coloured. It was slightly alkaline and contained a considerable amount of albumin (3 per 1000 Esbach). The specific gravity was 1006; the cellular elements were few but consisted solely of lymphocytes. Some of the fluid was incubated at 37° C. after Laugner's method and flocculi were withdrawn from time to time and examined but no tubercle bacilli were found. One cubic centimetre was inoculated upon serum agar and glycerine agar respectively. About 2·5 cubic centimetres were injected subcutaneously, two cubic centimetres intraperitoneally, and about one cubic centimetre intrameningeally into guinea-pigs. Three tests were made with a view of comparing the results, as there has been some discussion about the best method. (As yet there has been insufficient time to obtain results from the *culture and inoculation tests.) The cryoscopic point* was 0·53, as against 1·03 obtained from some hydrocephalic fluid which was in my laboratory. The chlorides (one estimation) were 0·177 per cent. as against 0·223 (five estimations) of [illegible] The permeability test was negative. It [illegible] have never once been able [illegible] the deposit. In four of the five cases lymphocytes were alone found and in one only polymorphonuclear cells. The inoculation test gave a satisfactory result in three out of the four cases and is as yet incomplete in the fourth case. The points of importance in the examination of the spinal fluid are the presence of the tubercle bacillus and lymphocytes in the deposit and the results of the inoculation test. I look upon the cryoscopic and permeability [illegible]

The finding of [illegible] the deposit is by far the best [illegible] It requires little time. It has given positive results in the hands of various observers up to from half to three-fourths of the cases. I look upon my want of success as a matter of accident. The inoculation test is ve[illegible] delay. Slawyk and [illegible] of four cubic centi[illegible] advises lumbar inoculation as requiring less fluid. No doubt negative results may be due to the use of too small a quantity of fluid but less quantities than those named above have answered my purpose. It is well, however, to be on the *safe side. I take it that, if an acid- and alcohol-fast bacillus* resembling the tubercle bacillus is found in the deposit from the spinal fluid obtained from a case with symptoms of meningitis, the nature of that meningitis is determined even should the inoculation test subsequently give a negative result. Therefore I do not quite see the reason for Chipault's[48] hesitation in certainty of diagnosis in a case subsequently to be referred to. The tubercle bacillus may be cultivated from the spinal fluid. Slawyk and Manacatide recommend the use of a fairly large quantity of the fluid for this purpose. Laugner (quoted by Hellendall[49]) incubates the fluid at 37° C. and in eight days there is a rapid multiplication of the tubercle bacillus. In one of the cases where I tried this method I obtained a considerable streptococcus growth which I looked upon as a terminal infection. Much has been written lately about lymphocytosis in tuberculous meningitis. It certainly badly misled in Rendu and Gerand's case.[50] Nobécourt and Voisin,[51] Simon,[52] and others have found it in cases of tuberculous tumours without meningitis. They look upon it as a sign of irritation of the membranes. If any polymorphonuclear cells are present as well as lymphocytes a differential count should be made as recommended by Achard and Laubry.[53] Leri[54] pointedly *remarks that if the clinical and cyto-diagnosis are not in* agreement the cyto-diagnosis is not always right. This applies to one of my cases though fortunately the inoculation test settled it. The study of the spinal fluid obviously yields results which are of the first importance in the differentiation of the various forms of meningitis. If aspiration is avoided and the fluid allowed to escape slowly there is no danger in it in meningitis and I see no reason why it should not be used as a routine method in suspected cases of these diseases.

RECOVERY FROM TUBERCULOUS AFFECTIONS OF THE NERVOUS SYSTEM.

Very occasionally one has the good fortune to meet with recovery from symptoms of grave organic disease of the brain where a tumour has been suspected and syphilis can with almost certainty be excluded. I have notes of two such cases treated in the Leeds Infirmary and possibly of a third. Recovery is often incomplete, blindness remaining. Some great authorities (such as Gowers[55] and others) say that in tuberculous tumours arrest is not uncommon. Presumably some of the recoveries referred to above may be of this nature. It is therefore interesting to inquire what pathological evidence is forthcoming in favour of this view. In two cases from the records of the Leeds Infirmary with healed phthisis there was in one a nodule in the left lenticular nucleus which Dr. Barrs regarded as a healed tuberculous lesion and in the other a calcareous mass of the size of a pea attached to the dura mater. Sufficient proof as to the exact nature of these lesions is not forthcoming. I have only been able to find in literature a few cases of recovery from tuberculous tumours. In Williamson's case[56] there was a small yellowish mass which had caused Jacksonian epilepsy four years previously, in Ashby's case[57] there was a small cyst with cretaceous walls, in Bristowe's case[58] a hard mass was present in the cerebellum, and in Kahlmeyer's case[59] a cicatrix was found in the cerebellum in a man who had cerebellar symptoms 11 years previously. In the first three cases *there were other masses in the brain* and the patients died from tuberculosis and in the fourth case there was phthisis. The quiescent lesion showed a dense fibrous capsule in the first three cases. Oppenheim[60] says that these tumours may calcify and then become encapsuled, as if encapsulation were, as it probably is, the most important event. Calcification is nearly always a very limited process in the mass and other encephalitic lesions, as Oppenheim points out, may calcify. By the kindness of the authorities of the London Hospital museum I have looked through a relatively large number of tuberculous tumours but I cannot say that I have seen any which could be regarded as definitely healed. The very slender possibility of recovery from a tuberculous tumour is no doubt established by the above-named cases, but, as Ashby[61] well points out, we must set off against this chance *the possible development* of other masses in the brain or

[61] Loc. cit.

the child may die from tuberculous meningitis or other form of tuberculosis.

In considering recovery from tuberculous meningitis a distinction must be drawn between the ordinary more generalised form and the limited meningitis *en plaque.* Monnier[62] and others strongly recommend operation for the latter when there are localising symptoms. Gee,[63] in his article on Tuberculous Meningitis, in 1868 graphically described recovery as a matter of science. Many great clinicians have related cases of recovery but up to recently the absolute proof was wanting unless the patient died later, when anatomical demonstration of the healed lesion was provided (Rilliet, Politzer, Barth,[64] Cadet de Gassicourt,[65] Carrington,[66] and others, and more recently Jannsen[67] and Rocaz and Cruchet[68]). Another proof, but not so satisfactory, is the presence of choroidal tubercles controlled by a skilled ophthalmologist (Dujardin-Beaumetz[69] and more recently Thomalla[70]). The presence of an unmistakeable tuberculous lesion such as phthisis elsewhere in the body, as occurred in the cases of Ouffier (quoted by Chantemesse[71]) and Chappet (quoted by Bouclier[72]), makes the diagnosis almost certain. Mr. E. Ward had a case in the Leeds Infirmary with tuberculous disease of the ankle in which the symptoms of meningitis developed. The child recovered, though unfortunately blind, and is still living.

Bacteriological proof of the nature of the meningitis has been provided in the cases of recovery recorded by Freyhan,[73] Henkel,[74] K. Barth,[75] Gross,[76] and Winkler and Gohl (quoted by Chipault[77]). Tubercle bacilli were found in the spinal fluid in all these cases. The diagnosis in the cases of Rocaz (subsequently anatomically proved by Cruchet[78]), Mottard (quoted by Bouclier[79]), and Sepet,[80] rests on the Courmont-Arloing serum reaction, the value of which is not by any means universally accepted. In his Bordeaux Thesis, 1903, Parrenin states that in October, 1902, the cases of Thomalla, Henkel and Barth were living and well, but that Gross's case had early phthisis; Freyhan's case was quite well when last heard of in 1899.

In inquiring under what conditions recovery has taken place it is only necessary to mention large doses of iodide of potassium, creasote, &c., without confounding cause and effect. Spinal puncture, though possibly of value in a simple meningitis (Hirsch[81]) is of quite doubtful utility in tuberculous meningitis. In the cases of Freyhan, Barth, and of Winkler and Gohl puncture was performed once in each, whereas in the cases of Henkel and Gross the puncture was repeated three times. Chipault[82] is inclined to attribute some value to it, but only a small quantity of fluid was drawn off in the case to which he refers. In Gross's case the patient felt much relieved after it. In my case referred to above, where three punctures were made, 63 cubic centimetres of fluid in all were drawn off but with no real effect. Excess of fluid is not responsible for all the threatening symptoms in tuberculous meningitis, as Peron[83] points out in his experimental investigations. Experimentally Martin[84] noted an improvement in a rabbit after withdrawing two cubic centimetres of fluid but it was only temporary. Some of my experiments were made with this object but mostly very little fluid was found. Operations have been undertaken for the relief of this disease by Lannelongue and Keen, quoted by Barlow,[85] Ord and Waterhouse,[86] Parkin,[87] Paget, Kendal Franks,[88] and others. A case under the care of Dr. Churton and Mr. A. W. Mayo Robson[89] has been quoted by some authorities as a possible recovery from tuberculous meningitis, although neither of these authors described it as such. I was resident medical officer at the time this girl was in the Leeds Infirmary and she attended my out-patient room with epilepsy for several years previously to her death which occurred last year. She was trephined on account of focal symptoms which it was thought might be due to abscess secondary to ear disease. The case was obscure and occurred during the influenza epidemic of 1889-90 In her subsequent history she contracted syphilis but never showed any manifestation of tuberculosis.

Notwithstanding the above-mentioned remarkable recoveries from severe tuberculous meningitis, the prognosis must still be looked upon for practical purposes as hopeless. If a benign type of disease really exists systematic examination of spinal fluid should bring it to light. With such a prognosis before us prophylaxis is worthy of the closest attention. The danger which a careless phthisical patient is in his own home has been placed beyond doubt (Cornet,[90] Coates,[91] and others). This danger specially menaces susceptible young children who crawl about the floor stirring up infected dust. The tubercle bacillus is inhaled and a potential infecting focus is established in the bronchial glands. *Dieudonné*[92] has actually found tubercle bacilli on the hands of children in phthisical homes. Clinical evidence has also furnished some striking examples (Variot[93] and others) in the same direction. The notification of phthisis with disinfection and the isolation in special hospitals of confirmed and careless consumptives (especially if there are young children in their houses) are indispensable steps in the prevention of tuberculous meningitis and general tuberculsis. I am glad to say that we are about to open a hospital of this kind in the centre from which I come.

The old adage that "prevention is better than cure" was never truer than in the case of acute miliary tuberculosis and tuberculous meningitis.

Presidential Address

ON

THE RELATIONS OF OPHTHALMOLOGY TO GENERAL MEDICINE AND SURGERY AND TO PUBLIC HEALTH.

Delivered before the Ophthalmological Society of the United Kingdom on Oct. 29th, 1903,

BY JOHN TWEEDY, F.R.C.S. ENG.,
PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY, UNIVERSITY COLLEGE, LONDON.

GENTLEMEN,—My first duty on occupying this position is to thank you for the great honour which you have conferred upon me by electing me President of this society. No one knows better than I that I owe this mark of distinction to your indulgent favour and not to any services which I have rendered, or can render, to the society. Be this as it may, I am deeply sensible that without your sympathy and goodwill it will be impossible for me to perform with any degree of efficiency the duties which you have intrusted to me. And I will at once put your compliancy to the proof. Upon my election I was somewhat disconcerted to find that it had been an unbroken custom of this society that the newly elected President should deliver an address. To the subtle suggestion that the time was come for establishing a precedent by omitting the address on this occasion our surgical secretary gently hinted that public opinion was not yet ripe for this new departure. Nevertheless, wishing to spare you the infliction of an address I at first thought that it might not be amiss if I culled some of the choicer thoughts from the addresses of past Presidents; but on reflection I thought it was scarcely fair to take these gems of thought from their logical context and from their literary settings At length a better alternative suggested itself—namely, that I should exhort all the members of the society to read or to re read for themselves *all* the addresses of my predecessors And indeed, seriously and in all earnestness this is what I do recommend There you will find some of the best thoughts of some of the wisest and most thoughtful men of our profession—Bowman, Hutchinson, Hulke Hughlings Jackson, Power, Argyll Robertson, Nettleship, Swanzy, Critchett and last in the order of time but not of merit, the late Dr D Little of Manchester The mere enumeration of these names at once awakens agreeable and even hallowed memories and intimates the high character, purpose, and mission of the Ophthalmological Society Among the past Presidents have been men not only foremost as ophthalmic surgeons in the three divisions of the kingdom but also two of the ablest and most accomplished of the general surgeons in this country, at least two who, in addition to their eminence as surgeons, enjoyed a considerable reputation as physiologists and one who stands almost pre eminent not only in this country but throughout the whole medical world as a philosopher and physician The presidency of Dr Hughlings Jackson must always be remembered as one of the most critical and significant events in the history of this society and I venture to hope that in the near future another physician, not, perhaps, of Dr Jackson's supreme merit—that is scarcely possible—but another physician, whether general or neurological, will succeed to this office The various qualifications of the several Presidents of this society afford striking proof of a catholicity of opinion and liberality of corporate constitution which I hope will never be materially altered, limited, or abridged

I may, perhaps, venture to remind the younger members that this society was formed 23 years ago by a small body of earnest men who were interested in the study and investigation of diseases of the eye, not merely as local affections but also in their relations to general disease and more particularly to disease of the cerebro spinal system These colleagues comprised ophthalmic surgeons, general surgeons, general physicians, and neurologists, and also physiologists to whom the eye must always be not only an interesting object of study but one of the most important avenues of knowledge I trust that the society will never lose the impress of its early constitution and of its primary intention and endeavour Soon will devolve upon the younger members of this society the duty of preserving and perpetuating the honourable traditions of the society unsullied and unimpaired During the 23 years which have elapsed since the formation of this society many of the original members have already passed away, the last to leave us being one who was teacher, colleague, and friend to many here—George Lawson—of whom it may be well and truly said —He was an upright man and one who feared God In the course of nature few of those of us who still remain will survive another period of 23 years Other times will bring other men and, perhaps, other ideas and other aspirations In the growing complexity of social and professional relations temptations may present themselves to narrow the scope of the operations of the society These temptations will, I hope be strenuously withstood, not only by the enlightened policy of those who practise as ophthalmic surgeons but by the controlling influence of those general physicians and general surgeons whom it is hoped the society will never cease to attract

Specialism, however, there must be In the evolution of thought, in the increasing differentiation of social and economic functions, and in the consequent subdivision of labour, the growth of specialism is inevitable, and indeed necessary The increase of knowledge, the elaboration of the means and methods of investigation, the more minute *differentia* of disease and diagnosis, and the complexity and potency for good or for evil of modern therapeutics, whether pharmaceutical or surgical must eventuate in a specialisation of knowledge and in specialism in practice This tendency is observable in the whole world of thought and action, in philosophy no less than in physiology, in politics and in economics, in architecture and in engineering no less than in medicine and surgery, but it behoves the more enlightened members of our profession to take care that our specialisation shall be the legitimate and reasoned outcome of the growth of knowledge, the separation, as it were of a subject in order to develop it to the utmost. More than any other specialty ophthalmology should be rational and rest upon the sure and firm basis of a wide and thorough general and professional knowledge When we consider the importance of diseases of the eye, their incapacitating character, their grave economic effects and when we observe the enormous difference between skilful and unskilful treatment it must be obvious that the ophthalmic surgeon for the efficient discharge of his duties needs a good mental equipment, great intellectual and physical resources, and a sound professional training He needs the *courage and the dexterity of the* surgeon combined with the learning and acumen of the physician Doubtless there are few of us who even approach this ideal But no one who does not keep this ideal standard of requirement constantly in view can be regarded as fulfilling his whole duty, either as an ophthalmic surgeon or as a good citizen

The exigencies of modern life preclude most of those who practise as ophthalmic surgeons from also engaging in the actual practice of so-called general medicine and surgery, but we may all keep in intellectual touch with the developments of modern medicine and with the general progress of pathological knowledge and all that this implies Ophthalmology is a subject at once so fascinating and so complex that there is always a danger that those who are attracted by it may specialise too soon and specialise too much I fear that there is even within the ranks of the profession, and still more outside professional ranks, an undesirable disposition to split up practical ophthalmology into two parts, the optical and medico surgical This disposition ought, I think, to be jealously resisted, not only in the interests of our Art but in the interests of the public health The eye is not as the mere optician is too apt to consider, only an optical instrument, it is a living organism, made up of the most elaborate and most highly differentiated structures in the body, in intimate and constant relation with the cerebro spinal system, the blood vessels, the lymphatics, and the other organic systems of the body, living the life of the whole body, observing its modes of nutrition, participating in its diseases, and responding to its various pathological manifestations No one, then, can safely or intelligently deal with even the optical defects of the eye unless he has an adequate knowledge not merely of the structure and diseases of the eye but of the various relations of the eye to the whole organism.

It is a maxim of English law that every accused person shall be deemed innocent till he has been proved guilty Now, in practical medicine we adopt, or ought to adopt, a maxim the reverse of this Every organ should be considered unsound till it has been proved to be healthy And of no organ is this so true as of the eye We owe it, then, to ourselves, we owe it to this society, we owe it to the public to maintain and to proclaim *hic et ubique* that ophthalmology is one and indivisible, an integral and essential part of the Science and Art of Medicine

Gentlemen, this society has hitherto maintained a high ideal of knowledge, of technical skill and of professional achievement I would fain hope that this ideal will never be lowered or tarnished, that with increase of years the society may increase in numbers, in importance, and in influence, and that after the lapse of another 23 years it will have attained a position in professional and public esteem even higher than that which it occupies to day

SOME POINTS IN THE OPERATIVE TREATMENT OF TUBERCULOUS DISEASE OF THE KNEE-JOINT.

By K W MONSARRAT, M B, C M, F R C S EDIN,

SURGEON TO THE NORTHERN HOSPITAL LIVERPOOL.

DURING the last three years of the cases of tuberculous disease of the knee joint which I have had under observation I have had occasion to operate on some 14 Of these I have been able to follow the subsequent history in 11 and to estimate the result of the operative procedure I wish to make these cases the subject of some remarks relative to one or two points in the operative treatment of the condition The extent and localisation of the disease present in these cases when first seen are shown in Table I

A summary of the table shows in three cases synovial membrane alone, in two cases synovial membrane, capsule, and ligaments; in one case synovial membrane, with ulceration of the cartilage; in two cases femoral epiphysis alone; in two cases femur, tibia, capsule, and synovial membrane; and in one case tibia, patella, synovial membrane, ulceration of femoral cartilage and capsule. In six cases the disease was primarily synovial and in five cases it was primarily osseous. This proportion is not representative according to some surgeons whose experience of the disease has been large.

TABLE I.

No. of case.	Disease present when first seen.
1	Internal condyle of the femur, internal tuberosity of the tibia, synovial membrane.
2	Internal condyle of the femur.
3	External condyle, outer tuberosity of the tibia, synovial membrane.
4	Synovial membrane, erosion of cartilage covering the femur.
5	Synovial membrane.
6	Synovial membrane.
7	Synovial membrane, fibrous capsule, and ligaments.
8	Outer tuberosity of the tibia, patella, synovial membrane, capsule, and femoral cartilage.
9	Synovial membrane, capsule, and ligaments.
10	Outer part of the lower femoral epiphysis.
11	Synovial membrane.

Mr. Rushton Parker in his article in the "International Textbook of Surgery" says "practically always the primary focus is in the bones"; Mr. W. Watson Cheyne says the primary centre occurs "probably more frequently in the bone"; Mr. A. E. Barker says "in the very young the femur is most frequently the starting point, next the tibia, then the synovial membrane, lastly the patella; the older the patient the greater the probability of the synovial membrane being first affected." Whatever the actual proportion may be it is plain that in a large number of cases arthritis is secondary to osteomyelitis. It is in connexion with this that I wish to make the first point of my remarks—the great importance of the early recognition of tuberculous foci in the neighbourhood of the lower epiphysis of the femur and the great value of early surgical interference dealing with it. In Cases 2 and 10 this was the limit of the disease when first seen and I will briefly relate the history of each.

CASE 2.—The patient, a boy, aged three years, was brought to hospital in February, 1900. In the previous September the mother noticed that the right "knee" was swollen although the child complained only occasionally of slight pain. When examined the whole of the lower end of the femur was enlarged, particularly that part corresponding to the internal condyle. Pressure over the front of the condyle caused considerable pain. The depressions around the patella and the general outlines of the joint were normal. The diagnosis was tuberculous osteomyelitis in the lower femoral epiphysis The limb was fixed on a Thomas's knee-splint of the ordinary pattern and the child attended the hospital as an out-patient but irregularly until the following November. The condition appeared to improve for a time, at any rate, and his symptoms became quiescent, but before admission in November the disease had insidiously invaded the joint. On Nov. 29th I performed an arthrectomy and found an irregular cavity in the internal condyle of the femur communicating with the joint and collateral destruction of the cartilage covering the inner tuberosity of the tibia; the synovial membrane was but little affected. The bone disease was removed with the spoon and the surface of the cavity was rubbed with liquefied carbolic acid; the synovial membrane was also removed by dissection. Two months later it was necessary again to open the joint; unhealthy granulation tissue was removed from the cavity in the internal condyle and carbolic acid was again used. The result—fibrous ankylosis—was satisfactory. The child developed tuberculous vertebral disease later from which he has also recovered.

CASE 10.—The patient, a boy, aged four years, was admitted to hospital on June 4th, 1902. For about a month he had complained of pain in his knee and the mother had noticed swelling for the same period. On admission the lower extremity of the right femur was enlarged, particularly the outer condyle; it was tender on handling and the skin covering it had a glazed appearance. The child was well nourished and had a healthy appearance. I decided to temporise and fixed the limb in plaster. By the end of three months it was evident that the disease was not quiescent, although the joint remained unaffected. I therefore decided to attack the disease in the epiphysis and did so on Sept. 20th. Some weeks after primary healing I removed some unhealthy granulation tissue by reopening the wound. The present condition is satisfactory and the joint remains sound and unaffected.

This case supplies a suitable commentary on the first. Had I in the first attacked the disease at once when it was confined to the epiphysis the child might now have a moveable instead of an ankylosed joint. I think it is sound surgery to deal with such a focus as soon as the diagnosis is clear without any temporising or treatment by rest and for the following two reasons: (1) it is difficult to estimate in any given case how near to the joint the disease has encroached and a short delay may just make the difference between escape and involvement of the joint; and (2) the focus is as a rule accessible and can be thoroughly dealt with.

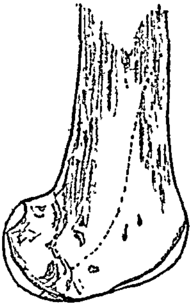
The recognition of this condition of tuberculous epiphysitis is simple: the symptoms being enlargement of the femoral extremity usually chiefly affecting the inner part, with some swelling of the overlying soft parts; complaint of dull aching pain; tenderness on handling or percussing the epiphysis and a normal distinctness of the para-patellar depressions. Passive movement of the joint is at the same time either unattended by pain or causes this to only a slight degree. I ask the question whether treatment by rest and general hygienic measures is not attended by unfortunate results in a considerable number of cases similar to the above. The indications for early operative treatment in a tuberculous focus of this situation differ from the indications for such interference when the disease is in the neighbourhood of the upper epiphyseal line, the difference being chiefly due to anatomical considerations. The tuberculous focus in the neck of the femur can in most cases be reached only through the joint, though cases are on record where such a focus has been reached and eradicated through the great trochanter. On the other hand, the focus in the neighbourhood of the lower growing line is accessible without encroaching on the joint and favourably situated in regard to drainage, though perhaps in most cases the latter will not be called for.

Amongst hospital patients it is, unfortunately, the exception to meet with these cases before the joint is infected and Table I. illustrates the fact. This, no doubt, is to some extent due to delay on the part of parents in bringing children for treatment but also, I think, to a too great confidence in the efficacy of treatment by rest and to the inadequate carrying out of instructions given by medical men.

Anatomically the most important point in operating on such a case is the outline and limits of the synovial membrane. I have constructed Figs. 1 and 2 from examinations on the cadaver which show the following points: (1) that in extension the lateral reflection leaves uncovered the greater part of the lateral and posterior aspect of the femoral condyle both externally and internally; and (2) that on flexion these aspects are almost entirely covered.

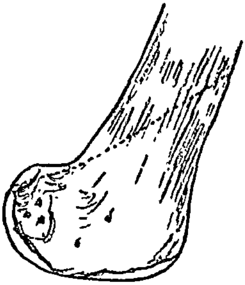
In Case 10 I gained access to the focus from the outer posterior aspect; a two-inch incision was made parallel with, and in front of, the biceps tendon downwards as far as the lower extremity of the outer condylar ridge; inwards and downwards from this incision the surface of the bone was reached to the inner side of the outer head of the gastrocnemius. In a similar case I would in future make an incision through the skin over the outer side of the condyle and having exposed the capsule strip this and the synovial membrane forwards; I have found on the cadaver that by this means ready access may be obtained to the outer aspect of the condyle without penetrating the synovial membrane. Inasmuch as the tuberculous focus is more commonly situated in the neighbourhood of the inner condyle a route from the inner side will more often be called for. Mr. W. Watson Cheyne recommends a curved incision with its convexity upwards at the junction of the condyle with the shaft; this outlines a skin flap which is turned up and a vertical incision through the muscular fibres towards the back of the condyle exposes the capsule which is stripped downwards. I have found on the cadaver that simple vertical incision similar to that which I have described for the outer aspect of the joint gives quite satisfactory access to the postero-internal aspects of the condyle. After exposing the bone the outer compact layer may be penetrated by a gouge or a spoon and the disease focus thoroughly scraped out. The cavity remaining should be treated with some satisfactory antiseptic, such as 1 in 500 biniodide of mercury in spirit; hæmorrhage may be checked by tight gauze packing for a few minutes and the wound may then be entirely closed without drainage.

FIG. 1.



Line of reflexion of the synovial membrane in extension.

FIG. 2.



Line of reflexion of the synovial membrane in flexion.

I wish next to refer to the results of treatment in the ten cases in which the knee-joint was opened: first, as to the recovery from the disease and, secondly, as to the subsequent functional value of the limb. The results as to recovery are shown in Table II.

TABLE II.

No. of case	Operation.	Interval since operation.	Ultimate result.	Remarks.
1	Erasion	2 years and 8 months.	Recovery.	—
2	,, (2)	2 ,, 3 ,,	,,	Pott's disease; recovery.
3	,, (2)	2 ,, 1 month.	,,	—
4	,,	2 ,, 1 ,,	,,	—

6	,, (2)	1 year and 10 months.	Recovery.	—
7	,,	1 ,, 10 ,,	,,	—
8	Excision.	1 year.	,,	—
9	Erasion.	10 months.	,,	—
11	,,	10 ,,	,,	—

By recovery I mean present freedom from local disease. In three cases in which recovery ultimately ensued I had to perform erasion twice; in one case (No. 5) the joint went to the bad altogether owing to septic infection. The history of this case is as follows. The primary erasion was done on Feb. 14th, 1900, and the patient was discharged with the limb in plaster on March 9th, primary healing having taken place. Unfortunately, he was not brought again to the hospital until the following May 25th and when the plaster was removed the wound was found to have reopened and was obviously infected. In spite of a second erasion it was never afterwards clean and I performed amputation through the middle of the thigh on April 5th, 1902, with a satisfactory result as far as his general condition is concerned. With regard to the other cases freedom from disease has been verified by the tuberculin test in Cases 2, 4, and 11; and the others with one exception I have seen within the last few months and there are no signs of recurrence. The exception is Case 7, which remained under observation for seven months after operation, up to which time no return of the disease had taken place. All that I wish to remark about these results is that they show that erasion is a satisfactory operation as far as recovery from disease is concerned, even if it be found necessary to repeat it. Such repetition must be due to the overlooking of some of the disease at the first operation. It is hardly necessary to say that asepsis is all-important and that a knee-joint the subject of mixed infection is practically doomed.

The second aspect of the result is the after usefulness of the limb for purposes of locomotion. The present state of the limb in these cases is shown in Table III.:—

TABLE III.

No. of case.	Present state of the limb.	Remarks.
1	Ankylosis.	—
2	Fibrous ankylosis.	Flexion corrected.
3	Bony ankylosis.	No flexion.
4	Fibrous ankylosis.	Flexion corrected.
5	—	—
6	Fibrous ankylosis.	No flexion.
7	(?)	,,
8	Fibrous union.	,,
9	Fibrous ankylosis.	,,
11	,, ,,	Flexion corrected.

It is almost of the nature of a surgical axiom that what is to be aimed at after erasion or excision of the knee is firm ankylosis of the joint. With regard to excision this is not only undoubtedly always the desired end but also in most cases attained without difficulty. With regard to erasion the question is more complicated. In the first place, after this operation, and in spite of a long subsequent immobilisation of the limb, an ankylosis that will resist all tendencies to flexion is not easily obtained; in fact, unless the union is one of bone it must always remain in doubt. With regard to the retention of mobility Mr. W. H. A. Jacobson says: "The frequency with which this has been obtained and its advantage have been in my opinion much exaggerated. I have no doubt whatever that a large number of published cases will show that where movement is sought for the risk is run of a certain degree of permanent flexion, of attacks of pain and swelling, and of the formation of troublesome sinuses. The argument against attempting to retain mobility in the joint is based therefore on two grounds: first, *the risk of permanent flexion* and, second, the *risk of recurrent disease*, and if these two risks can be avoided it may conceivably be justifiable to endeavour to obtain a functioning joint."

With regard to the question of flexion I may compare Cases 6 and 9 with Cases 2, 4, and 11. In the one group there was never from beginning to end any tendency to flexion; in the second flexion occurred and had to be corrected. In the first group I erased the joint by transsection of the patella with reunion of the fragments; in the second I opened the joint by dividing the ligamentum patellæ. From this comparison and on general grounds I believe that flexion is always likely to occur when the integrity of the extensor is interfered with and can be largely discounted by leaving this intact. If the extensor is thrown out of action the muscular balance is disturbed and the hamstrings and the gastrocnemius are given unnatural advantage, the only resistance to flexion being the illustrated. This criterion, valuable as it was for the last half of the nineteenth century, is now seen to be of less importance in judging of the nature of the disease than is the infection of the organism with Eberth's bacillus; whilst more recently even this bacillus itself is found to have congeners whose pathological relationships to the organism of man are yet undistinguished from that of Eberth's, and thus as a criterion of the significance of groups of clinical phenomena it has certainly ceased to be absolute. With Bretonneau the presence of false membrane on the fauces or upper air passages was a necessary antecedent to the postulation of the diagnosis diphtheria—a distinction long held—but Sanné in 1877 was already suspicious of the narrowness of this boundary and taught from his experience that there was a clinical entity that he called "diphthérie sans diphthérie." Klebs and Löffler by their bacillus set up a new standard of reference in this disease, a standard of great potential worth, which gave our views of diphtheria a catholicity that Bretonneau's forbade. No sooner, however, was a new tribunal erected than a mass of fresh difficulties were synchronously engendered and the path of the would-be dogmatic diagnostician is now at least as thorny as before. We now know that besides being present in the diphtheria throat the bacillus diphtheriæ may exist in an otherwise normal throat or in a throat which exhibits pathological changes quite unlike those of diphtheria, or even in a throat which is obviously the concomitant of a condition that is not diphtheria—scarlet fever, for example. These facts but exemplify in the domain of medicine the same principle that obtains in all departments of knowledge; absolute truth is an ideal, a metaphysical abstraction; finality is unattainable. It behoves one none the less to search for the greatest possible certainty, but this is unattainable by employing the methods of Procrustes, tempting as those methods are.

If we recognise that there are not, and cannot be, hard-and-fast lines in the biological sciences, that the types from which we learn are idealistic means, and that an organic continuity exists between all phenomena, we may find the illustration of this principle in the morbid states of the human body with very little application, and the purlieus of diphtheria, scarlet fever, and tonsillitis (using that word in its broadest significance) afford many interesting and instructive examples of departures from the type so various as to lead by an almost sensible mergence into one another.

If diphtheria be regarded for argumental purposes as at one end of a scale and scarlet fever at the other, and we confine our attention to the gradations between, we shall need to enumerate briefly those characters by which we are accustomed to differentiate the one disease condition from the other. Briefly, then, diphtheria is disease of a mucous membrane, generally of the throat and upper respiratory passages, proximately allied in its etiology with the pathogenic manifestations of the Klebs-Löffler bacillus, characterised by the formation of an exudation on the affected surface generally continuous in extent, inaugurated and accompanied by mild febrile phenomena, of short course, followed by great depression of the vital powers, followed also by a train of symptoms due to the absorption of certain toxic products of the metabolic activity of the Klebs-Löffler bacillus and to the degenerations of various tissue cells induced by those products, the more common of which are myocardial, central and peripheral nervous, gastric, renal, and hæmic degenerations.

Scarlet fever, on the other hand, is a disease in which, after preliminary invasion of the throat and upper respiratory passages by a certain putative coccal bacterium, certain inflammatory changes are caused in those tissues of which the most common is the formation of an exudation on the tonsils and fauces; by the passage of this coccus or its products into the circulation a dermatitis is induced, this dermatitis beginning in the upper parts of the body and proceeding to the lower and being generally punctiform in appearance and erythematous in nature; the disease onset is ushered in, and accompanied by, well-marked febrile symptoms; whilst, later, infection of many organs by pyogenic bacteria occurs, this being especially the case with the ear, the joints, the submaxillary lymphatic glands, and the kidney, in any of which organs marked inflammatory changes may ensue; the disease is followed, as a result of the early dermatitis, by the shedding of the cuticle, most characteristically of the palms and soles, and is not infrequently complicated by the supervention of rheumatism.

One is accustomed to speak, too, very freely of tonsillitis as though that were a specific entity in itself, and acute throat affections which present anomalous concatenations of symptoms that do not tally satisfactorily with the book features of any of the classical diseases are apt to be brushed contemptuously aside with the label "tonsillitis" affixed as a final designation. Yet what varieties of throat infections there are and what various organisms associated with them. Diphtheria itself is only a specific tonsillitis and there are myriads of other organisms that may affect pathologically the tonsil and throat tissues. The recognition of the relationship that exists between many of these organisms and the various pathological phenomena that present themselves to us in inflammatory faucial conditions has as yet made little progress; some, such as the pneumococcus, seem to have a fairly definite etiological relationship with certain clinical conditions, but in cultures from the ordinary case of "tonsillitis" we find cocci of many shapes, sizes, and forms, principally staphylococci and streptococci, with a smaller proportion of other micro-organisms such as sarcinæ and yeasts. It is impossible at present to assign a definite value to the presence of each or any one of these bacteria. The word "tonsillitis," then, as ordinarily used here must be taken as signifying an inflammatory condition of the faucial tissues with a discrete follicular exudation on the tonsils that yields on culture a growth of coccal bacteria indistinguishable morphologically from the pyogenic cocci, this condition being accompanied, *bien entendu*, by fever and its co-existing and consecutive disturbances.

These definitions must be regarded as not more than broad working bases upon which the subsequent framework may be erected and from what has been said already it is obvious that they are no more than tentative half-truths, used, as shillings are used, as current tokens the intrinsic worth of which is far less than their face value. They must constitute, however, our verbal currency for present purposes.

Now as it is necessary to start with some fixed points I have chosen the disease means that are conventionally known as scarlet fever and diphtheria and propose to take a line through another arbitrary mean—tonsillitis, distributing around and between these groups those cases that do not bear the absolute features of any of these and yet have relation, firstly, to each other; secondly, to some other group or groups; and thirdly, to the chief groups. In order to supply the mind with a graphic conception of these various groups, their coördination and inter-relationships, I have drawn up the accompanying simple diagram.

It must not, however, be assumed that any of the groups set forth in this diagram is a whit less arbitrary than any of the original or main groups; it is submitted that the exact opposite is the case; the aim is to illustrate the fact that between the more clearly defined means lie many less clearly defined means about which the less commonly occurring cases may be aggregated, and that each of these aggregations has relationships with one or more of the neighbouring aggregations. No single case of sickness is an exact replica of any other case of sickness any more than any particular man's face is an exact replica of any other's, and the best classification of disease (or physiognomy) will always be the most supple and comprehensive one. In the subject under notice it is only sought to point out how very imperfect and ill-adapted to its function the most elastic of classifications must of necessity be, for it cannot be contended that the groups indicated in the diagram are by any means all that might be formed.

In order to demonstrate the actuality of the signified groups I propose to exemplify each, whenever it may be necessary to do so, by reference to specific cases that have been under my observation, but it must be remembered that the instances given are only selected examples out of a wealth of material. In a turnover of a large number of cases of infectious diseases instances of these variations are always present and form a by no means inconsiderable proportion of the total bulk, and though it is necessary here to restrict oneself to one or two examples of each kind it would be easy to multiply these twenty-fold in most instances. For present purposes, too, it will be necessary to state the points of each case very baldly, giving only the briefest possible summary, though detailed clinical accounts would demonstrate the points urged far more luminously.

Scarlet fever itself has already been defined and its main features are so widely observed and so generally recognised as to call for no further description or exemplification. Not quite so well accepted are those cases which with some of

the traits of scarlet fever combine other characters not usually associated with scarlet fever, especially those in which the rash is ill-marked, fleeting, anomalous in appearance, or of unusual distribution, perhaps even combining one or more of these attributes. Often so little like scarlet fever are these cases that their relationship to that disease may be either overlooked by the most experienced or may be absolutely indeterminable. Nor will time always solve the question. If profuse general desquamation ensue in due course, especially if the palms and soles exfoliate their coating of epithelium in bulk, the diagnosis is practically certain, but from the nature of the original dermatitis it is improbable that this will occur and a little ill-defined peeling—or even none at all—may leave one in as much doubt at the end of the case as one was at the beginning. A legion of examples illustrating every phase of these conditions might be adduced, but one must suffice. It is chosen for the reason that it was so anomalous as actually to deceive and yet demonstrated its real character by its subsequent course.

CASE 1.—The patient, an assistant nurse, aged 22 years, had never had scarlet fever. 14 days after arriving at the Grove Hospital, during which time she was employed in a scarlet fever ward, she was taken ill with sore-throat, malaise, and fever. The tonsils and soft palate were swollen and injected and there was some speckly exudation on the tonsils. The tongue was moist and thinly furred. The submaxillary lymph glands were natural. The pulse was 84. On the evening of the third day some blotchy indefinite erythema, principally visible on the limbs, was observed. By the fifth day this had disappeared, never having presented any other characters than those mentioned. The soft palate was still a little injected and the fungiform papillæ were rather prominent. No organisms beyond the ordinary cocci were found in her throat on culture. By the eighth day the throat tissues were pale and free from exudation. Although in this case scarlet fever was strongly suspected at the onset, the subsequent course appeared to justify her discharge on the eleventh day with the diagnosis of tonsillitis. On the twenty-third day, however, she had pin-hole desquamation of the palms of the hands; on the twenty-fifth this desquamation was well marked and the fingers were peeling; on the twenty-ninth there were feathery desquamation of the toes and pin-hole desquamation of the soles of the feet, whilst the hands were peeling freely. During the whole of her illness she was under close medical observation.

It may appear that this case should have been regarded throughout with more suspicion than was actually entertained, but a somewhat extensive experience of sore throats among members of the staff of a fever hospital has taught one how extremely frequent these anomalous rashes are with every form of tonsillitis. The routine procedure that I adopt after examining a sore-throat is to inspect carefully the skin for any lesion that may be present, and I have been vividly impressed with the frequency with which erythemata of all kinds, shapes, and distributions occur in these circumstances. From a little mottling of the chest to the most intense general blush such rashes vary, and over and over again scarlet fever has been suspected where it did not exist. On the other hand, it is quite possible that many of these cases have been mild cases of scarlet fever in which the diagnosis has never been cleared up. The distinction is not possible with our present equipment—witness, for example, this case.

CASE 2.—The patient, a male, aged three years, was taken ill with sore throat and swelling of th[illegible] lands of the neck and was sent to [illegible] The throat was injected and swollen [illegible] nd exudation about the tonsils and [illegible] glands were a little enlarged and the tongue was coated with moist fur. The temperature was 99·8° F. On the trunk and limbs irregular, blotchy erythema was spread, showing some punctiform arrangement in patches. No diphtheria bacilli were found in two cultures of the throat, only the ordinary coccal organisms. By the fifth day the throat was clean but the rash persisted till the sixth and was followed by no desquamation except a little shagginess of the skin of the outsides of the legs on the thirteenth day. Altogether he was in hospital for 11 weeks, the latter part of the time because he had contracted measles.

Here, again, a large number of instances in point could be brought forward if space permitted, all cases of acute throat infections accompanied by erythematous rashes, none followed by peeling. The differentiation of such cases from the milder and less characteristic forms of scarlet fever is in our present state of knowledge impossible.

The ordinary throat infections, or instances of tonsillitis, have to be considered, too, in relation to a specific throat infection which is likewise unaccompanied by rash—I mean that form of scarlet fever that is known as "scarlatina sine eruptione." I long had grave doubts as to the existence of this condition as a distinct entity but I have seen it too often now to be able to doubt its actuality. The specificity of the condition can only be established by its occurrence in connexion with cases of undoubted scarlet fever with rash, and not only is this seen but cases are found precisely similar arising sporadically. Scarlatina sine eruptione usually comes to hospital with a certificate of diphtheria and if admitted to a diphtheria ward is very apt to inaugurate an outbreak of scarlet fever among the diphtheria patients; its recognition is, therefore, a matter of some little moment. On the whole it seems to affect the very young and the adult more than those inhabiting the age periods on which the scarlatinal incidence more commonly falls. Thus it happens that in an outbreak of scarlet fever in a family, whilst the children from, say, three to 12 years of age suffer from well-marked scarlet fever, the father or mother (who may have had scarlet fever when young) escape with tonsillitis (scarlatina sine eruptione) and the baby has a similar but more severe throat infection which is really scarlatinal also. As instances of scarlatina sine eruptione may be cited the following cases.

CASE 3.—The patient, a female, aged three years, was taken ill with vomiting, sore throat, and rhinorrhœa, and was sent to hospital as suffering from diphtheria. On admission the skin was pale. No rash had ever been seen by the mother or by the medical attendant. The throat was much swollen and injected and both tonsils were capped by patches of continuous white exudation. The mouth and the throat were filled with stringy muco-purulent secretion. The submaxillary lymph glands were much swollen and the tongue was thickly coated. Three cultures from the throat and the nose showed an abundant growth of coccal forms but no diphtheria bacilli. The temperature remained raised till the eleventh day; there were much delirium and restlessness and the tongue became ulcerated. Throughout the illness there was no desquamation. On the ninth day of the illness the patient's sister, aged 11 years, was admitted with well-marked scarlet fever with rash which was followed by desquamation in due course.

CASE 4.—The patient, a male, aged two and a half years, was taken ill with sore-throat, headache, shivering, rhinitis, and submaxillary lymphadenitis but no rash. He was brought to the hospital certified as having diphtheria, whilst his sister, who was taken ill at the same time, was sent in with ordinary scarlet fever. The boy had no diphtheria bacilli in his throat as evidenced by two successive cultures, in which, however, there were abundant growths of cocci. His throat was reddened and œdematous; a few specks of exudation were visible in the tonsillar crypts; there were much slimy secretion about the throat and abundant rhinorrhœa. The tongue was furred, there was no rash, and there was marked submaxillary lymphadenitis. It was not till the twelfth day of the illness that the fever subsided, when the throat became clean and the adenitis ceased. There was never any desquamation.

Two very similar cases were under treatment about the same time—a father, aged 41 years, and a son, aged 12 years, who in addition to these symptoms both showed the strawberry tongue.

These and such-like cases shade gradually into another condition that is very little dealt with in the systematic text-books and very little recognised generally but which is an almost daily experience in a fever hospital. I know of no heading in the official nomenclature to which they may be assigned and am forced to content myself with the inept designation "ulcerative tonsillitis." Not arising in association with any similar affection as a rule, these cases may or may not be infectious, but they are usually marked examples of throat infections and often run a severe, occasionally a fatal, course. Their chief character is the exhibition of a large ulcer or ulcers on the tonsils and surrounding tissues, some of considerable extent and depth; the adjacent lymph glands are inflamed and there are fever and general constitutional disturbance. The local process sometimes leads to considerable destruction of the throat tissues and the system may become infected by the pyogenic cocci. The great difficulty at first is the distinction of these cases clinically from diphtheria which they resemble strongly in the throat appearances; when this difficulty is disposed of by the progress of the case the suspicion of scarlet fever begins and is often, indeed, present to the end, so similar are the later lesions of the fauces and palate. The general symptoms, too, are of the sthenic type—delirium, restlessness, and considerable pyrexia—which suggest a much closer relationship to the latter disease than to the adynamic, algid diphtheria. The following cases are excellent instances.

CASE 5.—The patient, a female, aged two years, was taken ill with sore-throat, swelling of the glands of the neck, and constitutional disturbance and was sent into the hospital certified to have diphtheria. On admission she was found to have a temperature of 102·8° F.; there was no rash, the tongue was dry and furred, the throat was injected and a little swollen, whilst on both tonsils were masses of membrane-like exudation which on the left side overlapped the anterior pillar of the fauces and ran along the edge of the soft palate. The submaxillary lymph glands were a little enlarged and there was a little bronchitis. T[illegible] the throat showed various growths of cocci b[illegible] Before these had been made, however, she w[illegible] antitoxic serum. On the sixth day of illness the exudation began to separate and it was now seen to be composed of necrotic tissue covering ulcers in the subjacent parts. On the seventh day the slough re-formed but separated on the ninth day, leaving excavated, ragged ulcers of the tonsils and of the pillars of the fauces and soft palate. The temperature reached the normal line that night. The [illegible] ulcers occupied three weeks, the thro[illegible] earance till the thirtieth day. General [illegible] *pari passu* with the repair of the local damage. There was never any desquamation.

CASE 6.—The patient was a male, aged five years, who was taken ill [illegible] glands of the neck, and [illegible]
to have diphtheria.
[illegible] upper surface of the
[illegible] palate, extending on
[illegible] rane like exudation.
[illegible] rged and tender and
[illegible] sent. He was given
[illegible] hree cultures of the
throat, taken on successive days, showed growths of streptococci only. [illegible]
palate. There was no evidence of syphilis in this case and no further treatment than simple lavage with chlorine water was adopted. There was never any desquamation.

Closely as these cases resemble scarlet fever in their subsequent stages it occasionally happens that the parallelism is still further marked by the supervention of pyæmic phenomena, as took place in the following case.

CASE 7.—The patient was a female child, aged one and a half years. This case may cause some dissension from the fact that some diphtheria bacilli were found in the throat but the case was far removed
[illegible] appropriate
[illegible] with vomit-
[illegible] gh, and was
[illegible] On admis-
[illegible] overed with
[illegible] were much
[illegible] iorrhœa and
[illegible] both sides.
[illegible]
still unhealed sinus behind the right ear.

The resemblance of this case in which no rash was present to the severe form of scarlet fever in which there are combined local destruction of the throat tissues and septic infection of distant structures is well worthy of notice. Even without proceeding to the length of a general infection of such severity an ulcerative tonsillitis may be accompanied by an eruption of the skin which bears no distinctive character and is quite unlike the general eruption of scarlet fever These rashes vary widely. The following case may be taken as showing what may occur.

CASE 8.—[illegible] female, aged 21 years, was taken ill with
[illegible] and rash, and was
[illegible] On admission the
[illegible] red, macular rash,
[illegible] but composed of
smaller and more closely aggregated lesions. The throat was reddened and œdematous and showed a film of slough on the right tonsil The tongue was coated with thick fur. On the next day the rash had spread in extent; it had coalesced in places on the arms, was still discrete on the thighs, but was continuous on the legs. On the sixth day the rash was fading and the slough on the tonsil had separated, leaving an exposed ulcer. No diphtheria bacilli were found in three successive cultures and there was no desquamation.

The features of this group of cases that I wish to emphasise are that whereas the throat appearances are most puzzlingly akin to those of diphtheria the course followed by the throat lesion is very different, *for rarely indeed do we find* any ulceration, except the most superficial and transitory, in straightforward, frank diphtheria. This local necrosis of tissue divides this group of cases from the next which I have called, for the sake of convenience, "coccal diphtheria" (the *diphtérie à streptocoques* of Variot). I do not mean to imply more by this term than that a disease indistinguishable from diphtheria is not uncommon in which repeated cultivations of the throat fail to bring to light the Klebs-Löffler bacillus. The following case, *inter alia*, is in point.

CASE 9.—A female, aged 20 years, was taken ill with vomiting and sore-throat and was admitted to hospital on the next day certified to have diphtheria. The throat was reddened and œdematous; on both tonsils were continuous [illegible]

cultures were made fro[illegible]
discovered. The temp[illegible]
[illegible] any ulceration. The subsequent
[illegible] There was never any desquamation.

This form of illness may also be attended with eruption on the skin and also with laryngeal infection. The appended case exhibited both of these features.

CASE 10.—The patient, a male, aged two years, was taken ill with sore throat, swelling of the neck, and croup, and was sent to hospital as a case of diphtheria. On admission he was found to have a husky [illegible]

Having passed in review these several gradation forms from the standpoint of scarlet fever, it may be profitable to recommence at the bottom of the scale in the diagram, taking diphtheria as the fixed point and moving gradually in the direction of scarlet fever to reach the point where the two blend in the individual patient—that is to say, till those two arbitrary means are so commingled in the same subject that a fresh mean is established equidistant from each.

Of diphtheria *proprement dit* it would be supererogatory to speak; a definition has been hazarded; the condition is a well-known one and forms an admirable *point d'appui* for the argument under consideration. The only minor variety of diphtheria of which preliminary mention is necessary is one, too, that is so widely recognised that the production of individual instances would be tedious I refer to the state clinically indistinguishable from tonsillitis, in which culture of the tonsillar exudation shows diphtheria bacilli to be present in such large numbers as to make it reasonable to believe that this organism has causative alliance with the malady. The activity of this factor and the relationships of these sore-throats are among the many valuable results of the discovery of the bacillus diphtheriæ, though their nature was shrewdly suspected at least 25 years ago by Sanné, as has already been remarked. Having, however, referred to its occurrence, we may pass on to consider the association of the diphtheria bacillus with other organisms, especially the pyogenic cocci, in the production of illness.

It is matter for surprise that the part played by these bacteria—albeit subordinate to that of the protagonist, the Klebs-Löffler bacillus—attracts so little attention, for the modification in type-diphtheria which they introduce when taking an active share in the illness is a by no means negligible one. As has been previously remarked, diphtheria is a depressant, asthenic malady. When suffering from it the patient is quiet, languid, and *triste*; its course lasts but a few days, the temperature is but little raised, and the ancillary features of pyrexial disturbance are feebly marked. Quite otherwise is it with those illnesses in which the pyogenic cocci are much concerned. In them fever, restlessness, and delirium are present; the patient is active and struggling and the course is of uncertain duration. Regarded from another point of view diphtheria is, in the main, a toxæmia and even if the specific bacilli are scattered by the blood stream no fresh lesion is produced by the metastasis. The pyogenic cocci, on the other hand, tend to reproduce their lesions in different parts of the body and suppurations of various tissues, adjacent or remote, are common sequelæ of a septic infection. Now, although an attack of diphtheria in which a pure culture of the Klebs-Löffler bacillus is obtained is comparatively uncommon, the prevalence of that factor in the diseased condition can usually be gauged to a certain extent, even though other organisms be present. In a good many instances, however, diphtheria bacilli are present in comparatively small numbers, and though their functional activity may be undoubted from various signs and symptoms there is a deviation from type-diphtheria towards the condition naturally associated with septic infection. In such instances, whilst the throat appearances are akin to those of diphtheria, and diphtheria bacilli are present in the throat, there will be superadded various local and general effects which may be reasonably referred to the presence of the luxuriant growths of the pyogenic cocci that accompany and vastly outnumber these bacilli themselves. On such occasions will be looked for a marked rise of temperature, a longer and more irregular course, feverishness and delirium, persistent submaxillary lymphadenitis ending perhaps in suppuration, otitis media, and other septic lesions. Locally are seen without surprise a more marked inflammatory reaction in the throat tissues and perhaps some ulceration of those tissues when the membrane has separated. The proportionate part taken by the two factors varies greatly, of course, sometimes one element prevails much, sometimes the other; in some instances a fairly even balance is struck between the two. The following case illustrates some of these facts.

CASE 11.—The patient, a boy, aged three years, was taken ill with sore-throat, vomiting, and eruption on the skin, and was brought to hospital, under a certificate of diphtheria, on the fourth day of illness. Impetiginous sores were scattered about the face; there were several pustules on the neck and the left ankle and a whitlow of the left thumb was present. The throat contained much slimy mucus but when this was removed it was seen to be markedly swollen whilst membrane covered both the tonsils and the uvula. The left submaxillary lymph glands were considerably swollen and hardened, the tongue was thickly coated, and there was profuse rhinorrhœa. The child was delirious and restless; the temperature ran a continuous course between 103° and 102° F. till the fifteenth day and there were present during this time the usual febrile symptoms. Diphtheria bacilli were found in certain numbers in the nose and throat but there was an enormous number of cocci associated with them. By the tenth day the local symptoms had abated, the rhinorrhœa was less, the throat was less swollen, the membrane had separated, and some superficial ulceration of the tonsils was seen. *The right tonsil healed readily, but an* excavated ulcer of the left tonsil formed and the left sided lymph glands became harder and more painful and remained so for a long time. On the sixteenth day right otitis media ensued and this was followed by right otorrhœa.

Cases such as this are by no means infrequent and they illustrate very clearly the two disease elements at work, the diphtheria element and the septic element (if I may call it so). Every *nuance* in the association of these elements may be observed in the study of diphtheria patients and the relative importance of the two, both for purposes of diagnosis and of assessing their infectivity to others, is a matter that cannot be too carefully dealt with. Space will not permit the pursuit of these fascinating themes and we pass from it insensibly to the association of the diphtheria bacillus with another septic throat infection, in this case a specific infection—namely, scarlet fever. The nexus passes most naturally through those scarlatinal throat infections which have been spoken of above under the title of "scarlatina sine eruptione." When this variation from type-scarlet fever is associated with the presence of a certain number of Klebs-Löffler bacilli in the inflamed throat, especially when it arises sporadically, its distinction from diphtheria with prominent septic element and subordinated diphtheritic element may indeed baffle the most astute. The separation of such a case from one of ulcerative tonsillitis in which diphtheria bacilli are casually (as opposed to causally) present is, I think, impossible apart from collateral circumstances. Some of the difficulties that such cases of scarlatina sine eruptione with diphtheria bacilli in the throat may present are shown in the following case.

CASE 12.—A male, aged 13½ years, was taken ill with vomiting, sore-throat, headache, and shivering and was admitted to hospital on the next day certified to have diphtheria. On admission no rash was seen nor did any appear throughout the illness except as detailed below. The throat was œdematous and on each tonsil patches of membranous exudate were present. The submaxillary lymphatic glands were somewhat enlarged and the tongue was covered with dry, caked fur. The temperature was 104·2° F. A few diphtheria bacilli were found on culture from the throat, together with many cocci of various forms. The patient was given 12,000 units of antitoxic serum. On the following day the throat exudation had become continuous in extent, there was profuse rhinorrhœa, much stringy mucus blocked the mouth, and the submaxillary lymphatic glands, especially on the right side, were larger and more tender. There were much restlessness and delirium and the evening temperature was 105°. He was then given 18,000 units of antitoxic serum. On the fifth day of illness the tongue was clean, dry, glazed, and showed marked prominence of the fungiform papillæ, and there was an eruption of small discrete papules over the knees, the elbows, and the sides of the trunk. Delirium was very violent. The temperature was 103·6°. After this gradual improvement took place, the temperature reaching the normal on the eighth day, when also left otitis media, followed later by otorrhœa, occurred. The exudation cleared from the throat without leaving any but superficial ulceration. There was never any desquamation.

The true nature of this case might not have been revealed had it not been that the patient gave rise to a little epidemic in the diphtheria ward to which he was sent, in the course of which no less than ten patients developed scarlet fever, an occurrence which demonstrated pretty clearly that he had been suffering from scarlatina sine eruptione, complicated by the presence of diphtheria bacilli in the throat.

From such cases as these the transition is easily made to the group of cases in which well-marked scarlet fever, with its characteristic phenomena, occurs in association with the Klebs-Löffler bacillus. It is a great pity to lump these cases with others and to label them scarlet fever and diphtheria; such action implies that they are cases of diphtheria as much as of scarlet fever, whereas diphtheria itself is a disease of which the possession of Klebs-Löffler bacilli in the throat is only one feature and if any, or some, of these cases present no other feature of diphtheria than the possession of Klebs-Löffler bacilli in the throat the connotation becomes so narrow that the denotation (diphtheria) is worthless. If a routine practice be established of making cultures from the throats of all patients suffering from scarlet fever seen in succession it will be found that a large number have diphtheria bacilli along with other bacteria in the throat; the actual percentage varies with many circumstances—age, class of society, time of year, and so on—so that an actual figure, being so inconstant, is not of much account. A large enough number of cases will always furnish plenty of particular instances. This is a matter of such common experience as not to need exemplification. It leads, nevertheless, by insensible gradation to the consideration of the question whether scarlet fever and diphtheria can co-exist in a patient—both these conditions, that is to say, reaching their maximum at or about the same time. For scarlet fever to attack an individual recovering from diphtheria or diphtheria one recovering from scarlet fever is not only not surprising but is even a common event, especially in fever hospitals. There is no co-existence, properly so-called, about such events, for they succeed each other. For the synchronous occurrence of these diseases to be asserted in any instance there must be predicated for diphtheria some other attribute than the mere possession of Klebs-Löffler bacilli in the throat of a sufferer from scarlet fever; indeed, the finding of these bacteria even in an inflamed scarlatinal throat covered with continuous exudation in no way justifies an absolute assertion, as such a throat condition is quite consistent with the diagnosis of scarlet fever. Although some of these cases, doubtless, are instances of the synchronous occurrence of the two diseases, in order to assert the fact with any degree of assurance it is necessary to show that each element plays some part in the succeeding phenomena and it is very seldom that this can be satisfactorily accomplished. Here again, as in the argument of mixed infection by diphtheria bacilli and pyogenic cocci, we find much difficulty in apportioning its due share and influence to each of the elements involved, sometimes one being the leading feature, at other times the other. An equipoised coincident attack of diphtheria and scarlet fever I believe to be very rare—as rare, probably, as the contemporaneous efflorescence of two acute specific fever eruptions. Still, in watching many hundreds of cases of each disease instances are occasionally observed in which this occurs. Apart, however, from these, it is a matter of the greatest difficulty to assess the share that diphtheria bacilli take in the pathogeny of a condition in which symptoms of scarlet fever are pre-eminent and in many cases they probably exercise no traceable influence at all in the acute stage. Patients suffering thus may, however, infect with diphtheria bacilli fellow patients suffering from scarlet fever, which may result in their being attacked in their turn by diphtheria, and not improbably such patients may themselves suffer from diphtheria in convalescence from a rousing of the diphtheria bacilli in their own throats into activity by those extraneous influences which have this effect.

I have chosen the subjoined case, though owing to its late arrival in hospital the fact of the original scarlatinal rash is not well established, for illustration of the concurrent course of scarlet fever and diphtheria, for not only was the desquamation undoubtedly such as occurs after scarlet fever but the paralyses that ensued were of a character to warrant the assumption that the diphtheria bacilli found in the throat were of active pathogenicity.

CASE 13.—A male, aged 13 years, was taken ill with headache, sore-throat, swelling of the glands of the neck, rhinitis, and shivering and was brought to hospital certified to have diphtheria on the sixth day of disease. On admission there was well-marked coarse punctation of the outer sides of the arms and the same condition, but not quite so prominent, was present on the outer sides of the legs. There was also some erythema over the front of the neck due to poultices that had been applied. The throat tissues were much injected and very œdematous and continuous grey exudation covered both tonsils and pillars of the fauces, while similar but thinner exudation extended over the soft palate. The [illegible] iatic glands and the surrounding tissues w [illegible] d tender, and thin watery fluid ran from the [illegible] was 100·2° F. and the patient was delirious [illegible] s of antitoxic serum were injected. The first [illegible] diphtheria bacilli but one made on t' [illegible] T [illegible] d- [illegible] t. [illegible] superficial ulceration was observed. A macular rash appeared on the hands and feet—probably an early serum manifestation. [illegible] the patient became gradually bette[illegible] remittent and never rose over [illegible] throat resumed its natural app[illegible] and neck was noted on the t[illegible] desquamation was more genera[illegible] the hands. On the twenty-fift[illegible] soles of the feet were peeling profusely, as were also the trunk and limbs. On the thirty-third day there was paresis of the ciliary muscles. On the forty-first day paresis of the palate was noticed, [illegible] regurgitation of [illegible] This case surely [illegible] can both produce [illegible]

I have now shown, or endeavoured to show, that the principle of relativity obtains in a very striking degree in the knowledge possessed with regard to scarlet fever, diphtheria, and tonsillitis, and that it is a fatal error to suppose that anything approaching absolutism can ever prevail from the inherent nature and interdependence of these morbid states. The cleavages which time and circumstances have introduced into the series of beings of which biology treats have, to a certain extent, eased the labours of the systematist by fixing certain characters, with correlative sub-characters, and these are available for purposes of classification. Their kingdoms, phyla, genera, species, and what not have value in virtue of the distinctiveness of these factors. In medicine this is less so and in the subject of which we are speaking the interlacings, overlappings, and interfusions are such that no schema can be satisfactory, consistent or final. It is impossible to find the *fundamentum divisionis* for each group, in the absence of which the *differentia* of the species are only remarkable and not distinctive. The inference to be drawn then from what has been set forth is that no different characters of these morbid conditions, scarlet fever, diphtheria, and tonsillitis, are mutually exclusive, and that though these nosological terms may be employed for the sake of convenience and for the interchange of ideas they must not be deified into absolute entities. Such considerations as these have very practical bearings—bearings which bring us to no less a conclusion than that the diagnosis of these several conditions is an art with very severe limitations and it is wise, if humiliating, to recognise this fact. If the diagnostician have the broadest experience and the sharpest acumen he cannot assign a sickness to a group when no group exists for it, and if he grasp at once the nature of some of these cases he cannot place his particular case in a pigeon-hole when no pigeon-hole exists for its reception.

Much has been said of late, said glibly enough too, about errors in diagnosis in the infectious diseases. One wonders if it is realised by those who speak thus that, apart altogether from clinical difficulties, such as eliciting physical signs, recognising rashes, and so forth, there are an appreciable proportion of these cases which are undiagnosable. Such, nevertheless, is the fact, as I have endeavoured to point out, and its general recognition would be of great service. It is, indeed, only those who have not had considerable experience and given close attention to the subject who would expect every case to be referred to any of the three categories mentioned for any other than statistical purposes. The inherent impossibilities of such a course have not occurred to them.

Are experience and study of no value, then, in the diagnosis of these states? I think they are of very great value. Merely to realise the possibilities and contingencies involved in the examination of an individual case is to be on one's guard, and even though no definite diagnosis can be made the error of making a definite one is avoided. But there is more than this to be expected. If each case be intelligently regarded on its own merits and in the light of experience it will often be possible to say what no tyro can say—namely, that this or that particular case seems so far out of line from the generality of instances of diphtheria or scarlet fever, as the case may be, as to make it wise to treat it separately, and furthermore to err on the safe side therapeutically; as, for example, by giving antitoxic serum in a case that may possibly prove to be an aberrant one of diphtheria. One of the great difficulties in the administration of fever hospitals is the constant breaking out of scarlet fever in diphtheria wards and of diphtheria in scarlet fever wards, and in most instances such outbreaks can be traced to some individual the equivocal nature of whose illness had caused its real bearing to be overlooked. The mere fact of noticing that such a case was ambiguous would have prevented the outbreak. There are many minute points, often difficult to describe in language and quite impossible to impart fully, that one gets to look to for help after a time, and intangible as these may be to an outsider or one not constantly in contact with these diseases they are of great practical moment. The tint of the skin will often suggest scarlet fever; the comparative pallor of the throat diphtheria; decubitus, again, septic infection, and so on. After all has been said diagnosis in these diseases is only capable of being taught up to a certain point, and it is not till the knowledge has become intuitive that the fine points which suggest aberrance from one mean and approximation to another can be appreciated, and even this instinct is only capable of limited discrimination.

The fact remains, then, that the *nuances* between these conditions—scarlet fever, diphtheria, and tonsillitis—are so gentle that each shades off into the other not at one but at many points, and whilst this continues to be so, with the most consummate skill and the widest experience, the diagnostician can never attain a certainty in his art which its inherent disabilities forbid.

AN OBSCURE CASE OF INTESTINAL OBSTRUCTION DUE TO AN OBTURATOR HERNIA; LAPAROTOMY; ENTERECTOMY;

DEATH IN 27 HOURS FROM CARDIAC SYNCOPE AND PERITONITIS.[1]

BY JOHN R. LUNN, F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, ST. MARYLEBONE INFIRMARY, W.

THERE are few subjects of more interest than those which deal with the condition of the alimentary canal producing intestinal obstruction. I have therefore thought that the case which I am about to relate might prove interesting on account of the obscurity of the symptoms and of the rarity of the form of hernia and the absence of any localising symptoms which made it possible to form any accurate diagnosis beyond the fact that there was obstruction most probably involving the small intestines. This difficulty has appeared in similar cases reported. Most of such cases appear to have been females, the attacks were generally sudden, and there has not been much distension or tenderness of the abdomen. My case illustrates the fact that it is possible to empty the rectum and colon by enemata, although complete obstruction is present higher up. The patient's extreme obesity obscured any fulness in the thigh, though a hernia was looked for. She had her bowels opened naturally the day before admission into the infirmary but had not passed flatus.

The patient, a woman, aged 61 years, was admitted into the St. Marylebone Infirmary on the evening of Dec. 30th, 1902. She stated that she had always enjoyed good health until the 28th, when she had a sudden pain of an acute nature in the abdomen, followed by sickness, which vomit appeared to be the normal contents of the stomach. She had had no constipation nor had she passed flatus. On admission her general condition was good; she was very obese, weighing about 14 stones. Her pulse was regular, her temperature was normal, and her respirations were 20. Her tongue was clean and moist, the abdomen was not distended, nor had she any localised pain. The skin was slightly jaundiced. The patient had a right reducible femoral hernia and there was nothing definite to be made out on the left side. The rectum was emptied by means of an enema and the vagina was examined. She was dieted and given a mixture of bismuth and opium and a fomentation was applied to the abdomen. On the 31st another enema of warm oil was given to the patient but was not successful and nothing was felt by the rectum. She vomited some semi-digested food at intervals. On the evening of the 31st she began to vomit some doubtful fæcal matter, her tongue was dry, and her pulse was rather suggestive of peritonitis.

---

[1] A paper read before the West London Medico-Chirurgical Society on May 1st, 1903.

On Dec. 31st it was decided to perform laparotomy, before which the stomach was washed out and some very offensive matter was removed. The patient was given an injection of strychnine and morphia before the operation and she was well wrapped up. After the usual precautions had been taken the abdomen was opened in the middle line and its contents were explored systematically; the appendix was normal and the gall-bladder was not distended. On opening the abdomen distended dark small intestines presented at the wound which were covered with recent lymph. On tracing the distended gut downwards towards the left iliac fossa collapsed small intestines were seen, apparently bound down to the back of the os pubis, and while examining the intestines and surrounding parts immediately a flow of fæces welled up from the left iliac fossa; intestinal clamps were put on the intestines above and below where the fæces appeared to be escaping. On examination of the collapsed intestines (where the perforation seemed to be) they were found to be adherent to the parts just below the horizontal ramus of the os pubis, towards the direction of the obturator foramen. The upper part of the left thigh was examined just below Poupart's ligament and a distinct fulness was found on deep pressure internal to the femoral vessels. An incision was then made over the swelling and the tumour was found to consist of a piece of gangrenous omentum and was very adherent to the surrounding tissues. This was ligatured and removed; the ruptured sloughing intestines had been acutely strangulated at the entrance of the obturator foramen and on introducing the finger into the thigh wound it was found to pass into the abdomen through the obturator foramen. The clamped intestines were then brought up into the abdominal wound and it was found that the whole lumen of the strangulated gut was ulcerated through with the exception of about a quarter of an inch. The mesentery was stitched in the ordinary way and about two inches of the intestines were removed on each side of the perforation and a Murphy's button was introduced into the gut in the usual way. The abdominal cavity was thoroughly washed out with a sterilised saline solution at a temperature of 100° F. and was then closed with silkworm gut sutures. The wound in the thigh was drained with a small Keith's glass tube and iodoform gauze was passed through its lumen and the wound was closed in the thigh.

The patient stood the operation of two hours very well and she passed a good night; she passed flatus by the rectum. The temperature was 98·4° F., the pulse was 120, and the respirations were 20. She took some soda-and-milk by the mouth in small quantities at intervals of two hours during the night. On Jan. 1st, 1903, the patient's tongue became furred and she complained of abdominal pain She vomited some dark offensive fluid about 11 A.M. and died somewhat suddenly at 2 P.M. from cardiac failure and peritonitis.

At the post-mortem examination the small intestines showed signs of intense inflammation (peritonitis) and they were covered with lymph and some portions of the gut were in a gangrenous condition. The Murphy's button gave perfect anastomosis; the drainage tube was not blocked and had passed through the obturator foramen.

The sloughing condition of the gut in this case must have been produced by the arrest of the circulation and paralysis of the muscular coats; it is evidently unnecessary for the whole circumference of the bowel to be included in the stricture to produce strangulation, as in Richter's hernia; indeed, symptoms of strangulation occur when omentum only is contained in a hernia, which I myself have seen, a fact somewhat difficult to explain, as constriction of omentum by a ligature does not give rise to symptoms and most likely these cases of strangulation depend upon the reflex irritation of the omental nerves or upon a knuckle of intestine having been strangulated at the neck of the sac and having slipped back unperceived. The above case somewhat resembles one reported by my friend and late assistant, Dr. H. Sinigar,[2] which was not diagnosed during life, when a small knuckle of intestine not more than one inch in length was strangulated in the obturator foramen. The ring of the constriction showed that the entire calibre of the intestines was not included though the strangulation must have been very severe, as shown at the post-mortem examination by the sloughing condition of the gut. One of the difficulties of reducing these obturator herniæ is evidently due to the obliquity of the canal and the small size of its deep pelvic orifice. Mr A. A. Bowlby, C.M.G., points out in his Purvis Oration[3] that the absence of the passage of flatus is in all cases of greater significance than is mere constipation. Acute pancreatitis, volvulus, colitis, enteritis, gall-stones, appendicitis, and new growths were all considered before the operation as being one of the causes of the obstruction.

St. Marylebone Infirmary, W.

A CASE OF RETROPERITONEAL PELVIC SARCOMA.

BY JOHN McLACHLAN, M.A., B.C.L. OXON., M.D., B.SC. EDIN., F.R.C.S. ENG.

MR. J. H. TARGETT, assistant obstetric surgeon to Guy's Hospital, who made the microscopic examination of the tumour in the laboratory of the Clinical Research Association, regarded this case as so interesting and rare and of so great clinical importance as to deserve to be recorded in the pages of THE LANCET. No attempt is made to write a learned disquisition on the diagnosis of tumours of the abdomen—that "happy hunting ground" for elaborate clinical diagnoses—but simply to give a short record of what passed through the mind of a very ordinary general practitioner during the progress of the case.

The patient was an unmarried woman in her sixtieth year, though she looked much younger. I had seen her off and on for the last few years for various slight ailments, but there were no symptoms suggestive of pelvic disease, either of the pelvis itself or of its contents. It was only on Jan. 5th of the present year that something seemed to go wrong but it was most difficult to tell what it was. One very marked symptom was an unconquerable aversion to bread, of which up to that time she was very fond. One sometimes wonders whether such marked aversions or cravings for out-of-the-way things ought not to suggest to one that there is probably some trouble in the uterus or its appendages, or at least in their near neighbourhood, so near as to incorporate them in the mischief. I once had a case of undoubted cancer of the uterus where the patient was only happy when she had the coal-scuttle by her side and could break lumps of coal into small pieces, a great many of which she ate with evident relish. My patient being a maiden lady one shrank from suggesting a vaginal examination, nor, indeed, was there any special call to do so except that every other part of the body had been examined in the search for the cause of the symptoms but without success.

My patient did not complain of anything until Jan. 5th, when her appetite failed and she could not sleep and complained of not feeling well and of inward weakness and exhaustion, not able to talk or to bear being talked to. She had a feeling of great fulness but not much pain and could not lie on either side; after this she began to take to her bed. There was a slight evening rise of temperature and this fact, together with the great weakness and exhaustion, made me suspect that pus was being formed somewhere. I searched for it without success, once, indeed, inserting a hypodermic needle into a dull spot in the chest in case it might be an encysted empyema Some time after this I thought that the abdomen was increasing in size and it was very evident that the superficial veins on the lower part of the abdomen on the left side were much larger than those on the other side. The left iliac region also was dull on percussion and this dulness extended for a considerable distance in an indefinite way over the abdomen, but the right iliac region was quite resonant and remained so to the last. The position and extent of the dulness did not vary with change of position. Malignant disease of, or abscess in the region of, the cæcum was therefore put out of court once for all, as well as the existence of free fluid in the peritoneal cavity, at least to any appreciable extent.

Various questions now presented themselves: Was it a tumour, malignant or otherwise, of the left ovary? The dulness, which began in that region, and the enlarged superficial veins seemed to lend support to the idea that it might be malignant disease of that organ. I did not think it could be a simple ovarian cyst. Could it be malignant disease of the fundus of the uterus? Certainly not of the ordinary kind, though it might be a case of malignant disease starting [illegible] erus and the upper part of [illegible] and again there had been [illegible] elling discharge both from the vagina and the rectum. This, however, was by no means constant and was small in quantity. Was it some form of peritoneal cancer? The apparently sudden onset might have indicated the rupture of a malignant ovarian tumour and general infection of the peritoneal cavity. Was it a colloid cancer of the peritoneum? The patient had that special temperament with which I am wont to associate peritoneal cancers—intensely sympathetic, with a heart ever ready to bleed for the woes and sorrows of others. The absence of a well-defined growth, the softness, and yet withal some general tenderness of the abdomen seemed to lend some support to the idea of a generalised peritoneal growth. Soon after this, however, I was able to make out a definite central tumour which eventually reached the size of an eight months pregnancy and the dulness in the left iliac region disappeared. The tumour was rather tender to pressure so that one dealt very tenderly with it; this was specially fortunate, for the post-mortem examination showed that any rough handling must necessarily have resulted in rupture of some part of the tumour. I ought to mention, however, that for some weeks she had been liable to "heart attacks" and was unable to lie down in bed except at rare intervals and had to be propped up with pillows into almost a sitting posture. This I was inclined to attribute to reflex action due to irritation of the filaments of the vagus which I believe pass into the great sympathetic plexuses of the abdomen and pelvis and through them to the sexual organs. The post-mortem examination, however, showed that a more probable explanation was that it was due to a gradually increasing hydrothorax though both factors may have played a part. The dyspnœa was usually in the early hours of the morning and one can hardly understand why dyspnœa due to hydrothorax alone should vary in that manner. Further, the dyspnœa was much more severe and persistent in the early stages of the hydrothorax than it was when the hydrothorax had attained a large size. The chest was very carefully examined in the early stage of the illness for fluid or pus in the pleural cavities, yet one is apt to forget that though absent then there is no reason why it should not be present a month afterwards. The patient, however, was so feeble and so easily exhausted that one did not push the physical examination to too great a degree, more especially as by that time I had made up my mind that there was a malignant tumour in the abdomen. She was also very averse to any operation, even of the simplest character—preferred, in fact, to die a natural death. It was well, too, that no operation was attempted in this case, for any such attempt must have resulted in a surgical disaster of the most deplorable kind. It was well that I did not even attempt to tap it.

---

[2] Brit. Med. Jour., March, 1897.

[3] Ibid., January, 1903.

It may be of some interest to the Psychical Research Association to know that the month of April is a peculiarly fatal one to the family to which this lady belonged. During the last days of March we thought that it was impossible that she could live to see April, though her sister persisted in saying that she would. She did, and then, curiously enough, began to improve—the breathlessness lessened, the feeling of tightness in the abdomen was less marked, she could sleep better, she could lie down and was able to take more food and to enjoy it, and the desire for bread returned; all this even though the hydrothorax must have been increasing. It was thought now that she might live for many months, provided that the heart did not fail, for at times it was very weak. Suddenly, however, on April 30th, just after eating and enjoying a good dinner (for her) she rang her bell, and her sister on entering the room found her fighting for breath and just able to gasp out "air," "brandy," "water." She rapidly became deeply cyanotic and in a few minutes the struggle was over. On being told of the manner of her death I wondered whether it was due to sudden asystole, rupture of the heart, or pulmonary embolism.

Necropsy.—The examination was limited to the abdomen and thorax. Being in a private house and in the absence of skilled assistance the examination was not so minute as one would have liked. On opening the abdomen the first thing that struck me was the absence of the great omentum and the presence of a central tumour of the size already indicated rising up out of the pelvis. The tumour was very friable in parts, it being scarcely possible to handle it without rupturing some part; such ruptured parts to the naked eye had the appearance and consistence of thick porridge; there were also many cysts in it containing a bloody, grumous fluid, no doubt degeneration cysts. There was a small quantity of bloody fluid in the peritoneal cavity. The upper part of the tumour was white and firm and almost cartilaginous in texture. In the pelvis, where it had evidently originated, it was firmly attached to apparently the whole of the anterior aspect of the sacrum and could not be separated from it, and it was impossible to trace the large bowel or the great veins into the pelvis. The uterus was firmly welded to, and partly incorporated with, the anterior surface of the tumour, though its fundus and anterior surface could be easily traced. The Fallopian tubes were also firmly attached to the tumour though the ovaries were quite free. In fact the tumour occupied the space between the sacrum and the posterior layer of the broad ligament. On opening the chest the most striking fact was the small size of the lungs and next the large amount of bloody fluid in the pleural cavities, especially the left. Indeed, it was a wonder how the patient could have lived in comparative comfort so long with such a limited breathing surface. Had it not been that she was most carefully tended and nursed she could not have done it. The heart was small and flabby but there were no naked-eye appearances of fatty degeneration, though I regret now that it was not examined for "brown degeneration"; it was entirely free from blood clots and blood. I could not discover any sign of pulmonary embolism though the relations of the tumour to the iliac veins, together with the mode of dea [illegible]

Appended is " [illegible] the microscopic appearances of [illegible] f the specimen submitted to microscopic examination had an imperfect capsule of fibrous and unstriped muscular tissues. Histologically the growth was a soft spindle-celled sarcoma of loose texture. In some places the cells were arranged in interlacing bundles, in other parts they were irregularly disposed and widely separated, as in myxomatous tissue. Small nodules and strands of hyaline cartilage were found in the firmer areas, due to the chondrification of the growth. But the most striking feature of the section was the comparative abundance of polynuclear giant cells, or myeloids; as many as 20 of these large cells could be counted in some fields, especially where the growth had a softer texture. From these facts it may be concluded that the tumour originated from the periosteum of the spine or from some fascial structure in the pelvic cavity."

In conclusion, I would only add the query, Is it possible, or probable, that this tumour originated in a "dermoid cyst"?

Oxford.

ON THE VALUE OF ASPIRIN IN ACUTE RHEUMATISM.

By EDWARD MACKEY, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL; CONSULTING PHYSICIAN TO THE ROYAL ALEXANDRA HOSPITAL, BRIGHTON.

IT will be agreed, I think, that most practitioners treat acute rheumatism by salicylates in some form or dose and with good success as to the relief of pain, &c., but also with occasional drawbacks such as sickness, depression, or head symptoms. It was experience of these that led me to employ the acetic ester of salicylic acid (commonly known as aspirin) and with results which I think worth a brief record by the side of the many favourable reports from abroad. The remedy is now sufficiently known to make its description unnecessary here, but its advantages may be summarised in (1) its slightly acidulous, pleasant taste;[1]

---

[1] Dr. F. G. Hopkins in Hale White's text-book remarks on this point: "Salicylate of soda ($C_6H_4OH\ COONa$) has, as is well known, [illegible] sickly sweet quality. That this depends on the [illegible] that methoxy-benzoate [illegible] sweetness. This latter [illegible] erties of salicylates, but [illegible] ed by a negative (acetyl [illegible] rom sweetness ...... and [illegible] salicylates"—(i.e., aspirin $C_6H_4<OCOCH_3$).

(2) slight or non-decomposition in the gastric juice, so that it passes without causing nausea or irritation of the stomach into the intestine from which the active acid is absorbed; (3) consequent probably on differences in absorption and elimination there is much less liability to head symptoms, of which indeed the only one I have noticed, and that rarely, is tinnitus; and (4) less cardiac depression, so that although it lowers the pulse with the temperature it can be continued more steadily and with less anxiety than the soda salt. It relieves pain and pyrexia quite as well, if not better, but does not cause such copious sweating, although such effect is well enough marked after full doses.

Whilst not now discussing the etiology of rheumatism, whether meteorological or bacteriological—or the mode of action of remedies through nerve centres, or vaso-motors, or as antiseptic to microbes—a reasonable conclusion is that the disorder mainly results from unhealthy metabolism contaminating the blood and secretions with toxins, and such products as glycocine, which are neutralised by, and in the case of the latter combined with, salicylic acid, to form salicyluric acid, as which, or free, it is chiefly excreted.

Some observers—Osler, for instance—recognise little or no advantage in salicylates beyond some power in relieving pain (he gives only 15-grain doses), and Pribram and others state that cardiac complications are *more frequent* than under alkaline treatment directed to lessening acidity and fibrinous coagulation.[2] Fuller's proportion of cases in which cardiac complications ensued when treated with alkali was 1 in 48, Dickinson's (without alkali) 9 in 28, and statistics from St. George's Hospital show, of cardiac cases under salicylates 1 in 12 and under full alkaline treatment 1 in 54, though the duration of acute rheumatic symptoms was much lessened under the former.[3] Hence many authorities, W. Ewart, Luff, and Burney Yeo, advocate the giving of alkalies *with* salicylates, and this plan I have sometimes adopted with aspirin, though many writers object to the combination as incompatible. It is better to give the two remedies alternately at intervals of a few hours.

It has been plausibly argued that what is good for rheumatism of the joints is so for that of the endocardium, and therefore if aspirin or salicylic treatment is sufficient for the one it ought to be so for the other; but there are these points of difference—the heart cannot be rested and it is more exposed to the influence of the contaminated blood; so whilst agreeing with Burney Yeo that hospital statistics represent more than the *average* percentage of heart mischief in rheumatism, yet I think they indicate that it will be safer to conjoin both treatments in severe cases.

The following abbreviated notes are subjoined as illustrative. For some of them I am indebted to Mr. Foster and Mr. Henderson, house physicians.

CASE 1.—A youth, aged 17 years, was admitted into the Sussex County Hospital on Oct. 4th, 1901, with pain and swelling of the hands, the feet, and the knees, and a temperature of 103° F. He was ordered 20 grains of aspirin every three to four hours and a small blister to the right knee. On the 5th the temperature was normal; on the 6th it was subnormal. The patient was free from pain and was sweating profusely; he was ordered to continue the dose thrice daily; on the 11th once or twice daily, and to take hæmatogen for anæmia. On the 23rd he was well and was able to leave the hospital, the attack having been shorter than several previous ones.

CASE 2.—A man, aged 32 years, was admitted into the same hospital on Oct. 31st, 1901, with pain and swelling of several joints, pyrexia, sweating, &c. The attack first began nine days previously after exposure. He was ordered 20 grains of aspirin every three to four hours. He was relieved by the next day and on Nov. 4th was free from pain and the temperature became normal or subnormal and continued so. On the 18th he complained only of stiffness in the joints for which he was ordered alternate doses of iodide of potassium.

CASE 3.—A man, aged 25 years, was admitted into the hospital on August 7th, 1901, with his first attack of acute rheumatism. 14 days previously he had sore-throat; six days before he had pain and swelling of the ankles, the legs, and the shoulders; he was now very helpless and pain prevented sleep. His temperature was 102° F. and his pulse 92. He was ordered 30 grains of aspirin every four hours. On the 8th he slept well. His temperature was normal. He was ordered 20 grains pro dosi. Steady improvement continued and by the 15th he complained only of weakness in one leg and of depression. The pulse was 44. He was ordered effervescing potash mixture with quinine and ammonia and was discharged well on the 31st.

CASE 4.—A man, aged 34 years, was admitted into the hospital on March 15th, 1901. He had had several attacks of rheumatism since 1886. This one began three weeks before his admission. He got better but had a relapse four days ago with pain and swelling, especially of the wrists, and now had a systolic apex bruit and friction sound. His temperature was 103° F., his pulse was 120, and he was sleepless. 20-grain doses of salicylate of sodium every four hours were prescribed and he was better by the 19th, but he had a relapse on the 23rd and again, after improving, on the 30th. On April 3rd 15-grain doses of aspirin thrice daily were ordered with benefit. On the 11th, when convalescent, this was changed for quinine with iodide of potassium, but resumed next day on account of a relapse. He was not up until May 1st. In this severe case some comparison between the remedies is possible but aspirin was not given in doses large enough or continued so steadily as it should be.

CASE 5.—A man aged 44 years, was admitted into the hospital on Feb. 5th, 1901. His first attack of acute rheumatism occurred two years before; this one began with tonsillitis in December, 1900. He had now pain and stiffness in the ankles, the arms, and the shoulders. His temperature was 100° F., his pulse was 88, and he had a presystolic bruit, probably old. He was treated by aperients, opium, and salicylates in 20 grain doses and was much easier with a subnormal temperature on the 8th, but he had a relapse on the 20th when aspirin—15 grains thrice daily—was prescribed. On the 23rd he felt much better; his temperature was 99° but the heart's action was weak and the urine was alkaline. The medicine was reduced to twice daily. On March 4th quinine with iodide of potassium was substituted but a relapse occurred on the next day. Aspirin was resumed in *combination* with the last with relief and continued till he was discharged well on the 21st. In this case also the dose should have been larger and more continuous.

CASE 6.—A woman, aged 31 years, was admitted into the hospital on June 7th, 1901. She had had rheumatism at the age of 15 years. The present attack began five days previously with pain and swelling of the knees and ankles, sweating, &c.; now the temperature was 102° F., the pulse 120, and there was a systolic bruit. She was ordered 30 grains of aspirin, which dose was placed dry on the tongue; the second dose relieved all pain but the third irritated the stomach and was rejected. The quantity was then halved and taken readily in soda-water with a little brandy every four hours. (In other cases it was given with mucilage or a little acetic acid.) On the 9th she was free from pain and slept; her evening temperature was 100°. On the 13th she was doing well and the remedy, given now in sugared water, was reduced to twice daily. On the 20th some relapse occurred (the menses also) and it was again ordered every four hours. On the next day the patient was better and on July 6th she went out well. The bruit was not heard; during the last fortnight the patient had also had byno-hæmoglobin and citrate of iron with quinine.

CASE 7.—A man, aged 33 years, was admitted into the hospital on Dec. 16th, 1901. 14 days previously he had sore-throat, and for four days pain and swelling of the right foot, the knee, &c. His temperature was 102° F. and his pulse was 84. He was ordered 20 grains of aspirin every three hours and aperients. On the 17th the pain was much less and he was sweating profusely. The medicine was given every four hours. A blister to the knee was also prescribed. On the 20th he was free from pain. His temperature was normal. From the 23rd the dose was lessened and the temperature was subnormal and it remained so till he was discharged well on the 30th.

CASE 8.—A girl, aged 17 years, was admitted into the hospital on Jan. 3rd, 1902, with pain and swelling of the joints (mostly the knees and ankles) which began a month previously, when she went to bed for 14 days, then to work again, and soon relapsed. The temperature now was 100·2° F. and her pulse was 96. The tongue was coated and she was constipated and sleepless. The heart sounds were not clear and there were râles in the lungs with cough. She was ordered aperients, one blister, and 20 grains of aspirin every six hours. *On the next day the pain was* relieved and the temperature was normal. On the 5th the dose was ordered thrice daily and on the 6th it was lessened to 15 grains, the pulse being 60. The effective dose for such a case was thus lessened too soon and on the 8th some relapse occurred (the menses also). The 20-grain dose was resumed every four hours and, together with salicylate of opium lotions, quickly afforded relief. On the 15th, the pulse being again 60 and the temperature being subnormal, the dose was reduced to 15 grains thrice, and later twice, daily. On the 19th and 23rd slight relapses occurred, which yielded at once to increased doses. On the 19th stiffness of the joints only was complained of, which was treated by Tallerman-Sheffield baths and quinine with iodide of potassium. On Feb. 8th she was discharged well, except for slight valvular mischief, probably old.

---

[2] Nothnagel: Spec. Pathol. u. Therap., Band v., S. 99.

[3] THE LANCET, March 17th, 1900, p. 761, et seq.

CASE 9.—A girl, aged 18 years, was admitted into the hospital on Jan. 20th, 1902 She had had a previous attack of acute rheumatism when seven years of age; the present one began a month previously, but she had kept up till the last three days. She complained of pain in the feet, the wrists, and the hands. Her temperature was 101° F. She was constipated and had a coated tongue. There were effusion in the left knee and a systolic apex bruit, probably old. She was ordered aperients and 20 grains of aspirin every three hours. On the 21st her temperature was normal, her pulse was 76, and the pain was much less. On the 23rd her temperature was subnormal and her pulse was 68. On the 25th her temperature was 97·2° and her pulse was 68; she had little pain, so the dose was halved. On the 29th the treatment was alternated with iodide of potassium for stiffness. On Feb. 11th the patient was discharged well, except for the bruit.

CASE 10.—A youth, aged 17 years, was admitted into the hospital on Jan 17th, 1902, with his first attack of acute rheumatism of one week's duration. His temperature was 102·4° F. and his pulse was 72. He had a systolic apex bruit and there were pain and swelling mostly in the ankles and the knees. He was ordered 20 grains of aspirin every four hours, a blister to the knees, and an aperient. On the next day he was much easier, his temperature was subnormal, and his pulse was 60. He was ordered to alternate an alkaline iodide with the aspirin, and a blister to the region of the heart. He progressed well till Feb. *7th, when tonsillitis occurred. He was con*valescent on the 14th, when syrup of hydriodic acid was substituted and he was discharged on the 20th, the bruit only remaining.

CASE 11.—A man, aged 38 years, was admitted into the hospital on Feb. 10th, 1902. In July, 1900, he was an in-patient for three weeks with acute rheumatism and mitral affection; he was treated by salicylates and the temperature fell from 102° F. to normal in 36 hours. In *August he was readmitted for another three weeks and* again in October till the middle of December. with relapses which were more or less controlled by salicylates. (His father died from rheumatism and his brother has it.) Three weeks before admission he had sore-throat; one week previously the feet and legs became painful and then other joints. The patient was sleepless and his temperature was 103°. He had a systolic apex bruit and an increased area of cardiac dulness. He was ordered 30 grains of aspirin every *four hours and a blister to both knees. On the next day,* after five doses, he had great relief, "much more," he said, "than from salicylates." His temperature was 96 4°, his pulse was 80, and there was no marked depression. He was ordered to halve the dose. On the 12th the patient perspired much in the night; he was now free from pain: the temperature was subnormal and the urine alkaline, with a specific gravity of 1020 On the 15th the bruit was as before; the dulness was normal. The aspirin was continued every six hours, then thrice daily, and he recovered well without relapse, being up on the 21st and out on March 2nd. He has, however, been readmitted once since then to go through a similar experience.

Considerations of space prevent the printing of notes of some 30 or 40 somewhat similar cases, including some of pleurisy and neuralgia Subacute and chronic cases react less favourably, but the preceding suffice to show the power of the drug to relieve without discomfort and also the necessity of using sufficient doses continued sufficiently long if relapses are to be avoided.

Hove.

THE PREVENTION OF THE RECURRENCE OF NASAL POLYPI.

BY EUGENE S. YONGE, M.D. EDIN.,
HONORARY ASSISTANT PHYSICIAN, MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.

THE pathogenesis of recurrent nasal polypi, together with that of the primary growths, is still somewhat involved in mystery. It is true that the attractive field of speculative pathology has been diligently tilled, but with a few exceptions I do not think the harvest of definitely proven facts has been a very rich one. On the other hand, a study of this interesting subject, both in this country and on the continent, has convinced me that in the matter of the evolution of successful methods of treatment the labours of the clinical *observer have been distinctly more fruitful. By successful* methods of treatment I do not mean those procedures only which have for their aim the mere initial removal of the polypi, but rather those whose object it is to prevent the tendency to recurrence which these growths exhibit in such a marked degree. In some instances the recurrence of nasal polypi is only apparent and is due to the inaccessibility of their site of origin. The growths seem to arise most commonly from the concavity of the middle turbinated bone, *from the lower part of the infundibulum, the uncinate* process, or the bulla ethmoidalis—in other words, from the region of the middle meatus. Less frequently they may spring from the long free border of the middle turbinal. When, therefore, all visible polypi have been removed from the nose, others may still be packed away in the recesses under the middle turbinal and may rapidly enlarge and develop after pressure has been removed.

Polypi tend to return so long as any polypoid tissue is left, so that the removal of all such residual tissue which may be visible with forceps, snare, galvano-cautery, or chromic acid is a necessary part of the treatment. The cauterisation of the particular pedicles of the excised growths is recommended by some authorities but this manœuvre has, in my experience, been very frequently impracticable as the growths often sprang from areas which were hidden from view. The coincidence of polypi with suppuration in the accessory sinuses, especially the ethmoidal cells, is a common one. One observer[1] *believes that nearly all cases* of nasal polypi are due to suppuration in the sinuses, but this conclusion is not in accordance with the experience of the majority of surgeons; the polypi have, indeed, in some instances been considered to be the cause of the sinus disease, chiefly by preventing free drainage from the cavities. It would be possible to quote a considerable number of instances within one's own personal knowledge in which the two conditions of sinus disease and polypi had been found in the association of probable *cause and effect but the following* may serve as examples.

CASE 1.—A man, aged 25 years, was sent to me at the Hospital for Consumption and Diseases of the Throat for obstruction of the left nasal cavity, discharge of pus from that side, and unilateral headache. The cavity contained several large polypi and [illegible] of the left frontal sinus and of the [illegible] obstruction had not bee[illegible] the nasal discharge *had begun to be troublesome.* A modified Kuhnt's operation was done on the frontal sinus and the anterior ethmoidal cells were also curetted. When last seen, one year after the operation there had been no recurrence of the polypi

[illegible] year [illegible] on [illegible] to an attack of inflammation in the left sphenoidal sinus and posterior ethmoidal *cells 18 months previously from* which time he dated his nasal symptoms. The nose had gradually become blocked on the left side and at the time of examination the obstruction was very marked. A collection of polypi was found towards the posterior part of the cavity projecting into the naso pharynx The polypi were removed and the posterior ethmoidal cells were curetted. Great relief was experienced and up to the present there has been no recurrence either of the growths or of the suppuration.

---

[1] Grünwald: Nasal Suppuration. Translated by Lamb London, 1900.

CASE 3.—This patient was a man, aged 32 years. There were a small collection of polypi on the right side and empyema of the corresponding antrum. The polypi were removed and the antrum was opened by alveolar puncture. The polypi recurred later. Six months after the first operation, as the antrum had not healed and the patient was anxious to get rid of the discharge, the radical (Caldwell-Luc) operation was performed and the nasal cavities were again treated. When last seen (six months after the last operations) the patient appeared quite cured of his nasal and antral disease.

Lambert Lack[2] has comparatively recently made some valuable observations on the origin and the radical treatment of polypi. He believes that these formations usually owe their origin and their tendency to recurrence to disease of the underlying bone—the morbid condition being an osteitis and a periostitis of the ethmoid. These observations have been practically confirmed by Thurston, Martin, Cordes,[3] and others, although the last-named writer (Cordes) did not in his investigations always find bone disease in mild cases of polypi on microscopic examination. The growths, therefore, according to the foregoing theory, do not arise as independent morbid formations but are of the nature of outward and visible signs of morbid processes in the subjacent bony tissues. Clinical testimony in support of this statement appears to be provided by the fact that the inclusion of a portion of underlying bone, when removing a polypus with the snare, is found to be of distinct value in reference to the prevention of recurrence. Still further evidence is forthcoming in the excellent results in many cases of systematic treatment of the whole bony area from which the polypi grow.

It is a matter of common experience that when the polypi are few in number, are of long standing, and are not complicated by sinus suppuration, treatment with the snare will often effect a cure. In these instances the initial bone disease may be presumed to have subsided. More commonly, however, and especially if the growths are numerous and a radical cure is wished for, further treatment will be required. When all visible polypi have been removed it will be necessary to expose the parts from which they grew and to cut away the diseased tissues. This will probably involve as a preliminary the removal of a considerable portion of the middle turbinal or of what represents that structure. With local anæsthesia the undermentioned procedure[4] has seemed, in my experience, to be the most rapid, the most effectual, and the least painful method of carrying out what is desired. The manner of applying the cocaine is of importance. Two long strips of sterilised gauze are dipped in 20 per cent. cocaine solution; one of these is inserted between the middle turbinal and the septum, the other is pushed within the concavity of the turbinal, well into the middle meatus, and a third strip is insinuated between the former two under the inferior border of the turbinal After a lapse of ten minutes the operation is commenced. Luc's flat nasal forceps of the largest available size is introduced into the nasal cavity, passed to the insertion of the middle turbinal, and the portion seized is twisted and rapidly withdrawn. The major part of the turbinal can be removed by three or four such applications of the forceps, which should be made in rapid succession, the whole process only occupying a very short time. After drying the parts by packing with gauze the region which has been exposed by the removal of the turbinal can be examined and polypoid remnants and other diseased tissues removed by the same forceps or by a ring knife. Luc[5] additionally advises the opening of the posterior ethmoidal cells at the same sitting with his forceps.

The results of this procedure, with regard to the prevention of recurrence, have been very favourable, cases being cured in two, or at most a few, sittings, which would otherwise have had to endure weeks of treatment. If a recurrence does take place it is not of a severe nature and is usually more easily treated than is the primary condition on account of the modification which has taken place in the anatomy of the parts Other methods differing in detail but having the same object as the above—viz, the treatment of the parts from which the polypi grow—have been attended with good results General anæsthesia may, if necessary, be employed.

Lastly, the most advisable method of treatment for severe cases of multiple polypi, with a history of several operations for their removal, is still somewhat *sub judice*. On the one hand, there is little doubt that when polypi are thoroughly removed in the ordinary way the intervals between the recurrences in certain cases tend to become longer and longer. On the other hand, one knows of instances where it has been felt necessary to clear out the nasal passages at comparatively short intervals for a period of years. For the severer cases of polypi, especially if associated with suppuration and extensive ethmoidal diseases, Lack[6] has recommended a procedure which, briefly stated, is as follows. Under a general anæsthetic all polypi are removed, as is also the middle turbinal if still present. When there are many polypi but the extent of the disease is unknown, Lack advises commencing treatment by removing some of the larger growths with the snare under cocaine. This often enables a better view of the parts to be obtained and a more accurate estimate of the extent of the disease to be formed. The essential part of the operation is the thorough scraping of the lateral mass of the ethmoid with a large ring knife, by which large masses of polypi, degenerated mucous membrane, and fragments of bone are got away. Scraping is continued until all friable tissue is removed, the finger being introduced from time to time to ascertain the condition of the parts and the progress made. The field of operation is undoubtedly a perilous one, the vicinity of the cribriform plate being especially worthy of respect. It is, of course, highly advisable that the operator should have a very intimate knowledge of the region and that he should carefully abstain from using any force in an upward direction; also that a large ring knife should principally be employed. My own experience of this operation for severe cases of polypi, although somewhat limited, has, on the whole, been very encouraging. In no instance have any dangerous symptoms occurred. A temporary black eye has resulted on one or two occasions and in a case at present under observation there was after the operation a considerable outgrowth of granulations in the right nasal cavity which looked like a rapid return of the disease. These, however, have become considerably less and seem to be in process of spontaneous disappearance. The operation would not appear to be applicable to elderly patients.

Manchester.

ON THE NATURE OF CURSCHMANN'S SPIRALS.

BY E. E. LASLETT, M.D. VICT., B.SC. LOND.,
SURGEON TO THE HULL AND SCULCOATES DISPENSARY.

CONSIDERABLE difference of opinion still exists as to the nature of the spirals present in the sputum of asthmatic persons. Dr. J. F. Goodhart in his article on asthma in Allbutt's System of Medicine[1] expresses the opinion that they are allied in nature to the plugs in the sputum of plastic bronchitis. So far as I have been able to find he is the only writer who holds this opinion. I have for some time had under observation a patient who suffers from asthma-like attacks and whose sputum presents features which lead me to believe that some forms (if not all) of the spirals are, as Dr. Goodhart suggests, of similar origin to the casts of fibrinous bronchitis.

The patient is a woman, aged 26 years, of delicate constitution. There is nothing of special interest in her family history. She first began to suffer from attacks of dyspnœa 18 months ago. At first the attacks occurred at rare intervals but gradually they became more frequent and prolonged until at one time she was almost constantly troubled with wheezing and troublesome cough and the more severe attacks occurred at intervals of about a fortnight. The patient was always forewarned of the onset of an attack by a feeling of tightness in the chest with diminution, even to cessation, of the previously abundant sputum. This discomfort increased during the day until towards midnight the dyspnœa became severe and the cough had

entirely ceased. After an interval of from 12 to 24 hours the cough reappeared, the difficulty in breathing gradually subsided, and the characteristic sputum gradually increased in quantity. Cyanosis was never marked but the distress was severe, with profuse perspiration and subsequent prostration. During the next day or two cough was frequent and the sputum was very copious but afterwards gradual improvement took place, though the bronchitic symptoms never really disappeared before another attack occurred.

The most striking characteristic of the sputum is the large number of Curschmann's spirals present. Shortly after an attack as many as a dozen are coughed up in the course of 24 hours, but they gradually diminish in number until shortly before the next attack only one or two are coughed up in the same interval. Associated with these spirals there are casts of the smaller bronchi. These I have never observed very complete in their branchings. The parent stem is usually of about the diameter of a crow quill and may or may not have small side branches but it always divides dichotomously and the resulting divisions again branch, but further than this I have rarely seen, and the casts in this case have never shown the finer ramifications of the bronchial tree seen in the very complete specimens that have been described. Nevertheless, there can be no doubt about the nature of the plugs in this case.

Examined in the fresh state the parent stem of the casts appears to be practically solid but the branches are hollow. This is also well shown by hardening in a mixture of equal parts of methylated spirit and glycerine and subsequently soaking in 50 per cent. glycerine which swells up the tissue, shrunken by the action of the spirit, to its former size. By this treatment the arrangement of the branches is well preserved and their tubular character is quite evident. A portion of the main stem hardened in alcohol, sectioned in paraffin, and stained, shows a structure of irregularly concentric layers probably of a fibrinous nature in which are embedded numerous nucleated cells. In the fresh state the smaller branches show a well-marked spiral arrangement indistinguishable practically from that of the true spirals. In the parent stem this spiral arrangement is absent. The spirals resemble those figured in von Jaksch's[2] "Clinical Diagnosis" and are all of the coarse variety without a central thread. The spiral markings both in the casts and in the true spirals seem to be due to the arrangement of the cells as much as to the spiral mucus (?) threads. The cells, which are very numerous and of varying size and character, are arranged in the form of a dense spiral band. Many of them show eosinophile granules.

There is one important point which has not, I believe, been previously described. I have noticed that some of the spirals show a division into two distinct branches at one end. There is no doubt of this. Spirals often interlace in a manner which suggests branching but is not really so. In true division the branches occur at the end of the spiral, are short (about one centimetre) and of equal length, and are not more than half the diameter of the main stem. Weak alkalies dissolve the greater part of the translucent envelope of the spirals as of the casts, leaving a much finer thread which retained the spiral arrangement quite unchanged. This is no doubt due to the fact that the spiral is so largely formed by organised cells which are unaffected by the weak alkali. Strong solutions of caustic potash dissolve both casts and spirals almost completely.

The present case appears to be, if one may use such a term, a "half-way house" between true asthma and plastic bronchitis. The character of the dyspnœa—forced inspiration followed by very prolonged and difficult expiration—is that of asthma. On the other hand, the long duration of each attack and the presence of true casts in the sputum point to fibrinous bronchitis. It is well known that occasionally spirals are found in the sputum of patients suffering from the last-named disease (Osler[3]), and also that fibrinous casts sometimes show spiral markings on their terminal branches. In my case the spirals are undoubtedly the more prominent feature of the sputum.

The following quotation from Hoffmann[4] is of interest in this connexion: "I am forced to assume that the terminal branches of the bronchial tree end in spirals. For when we consider that in the act of inspiration the lungs are distended and that the bronchi must follow this distension, can it be imagined that a long straight tube should be distended longitudinally? It is much more probable that they resemble corkscrews and it is thus readily explained how the bronchi can follow the distension of the lungs. A very beautiful metallic cast of the bronchial tree which I saw at the Leipsic Pathological Institute shows this corkscrew like course of the larger branches of the bronchi and suggests the assumption that the finest branches have a similar course. ...... It is now understood how the fibrinous casts which originate in the fine bronchi occasionally show a spiral arrangement."

The most generally accepted theory of the formation of asthmatic spirals is that they are due to a twisting movement given to a mass of mucus in one of the bronchial branches. Yet it is difficult to understand how this spiral movement may arise. The present case leads me to suggest that these structures are in reality casts of the smaller bronchial branches similar in nature to the casts in true plastic bronchitis. In support of this theory I may draw attention to the following points: (1) fibrinous casts frequently show spiral terminations; (2) these terminal spirals are practically identical in structure with the true Curschmann spirals, also present in the sputum; (3) the spirals, at least in this case, owe their peculiar structure largely to the arrangement of the great number of cells present; and (4) some of the spirals terminate in two equal branches of smaller diameter than the parent stem. This fact alone makes it difficult or impossible to believe that these structures are formed by a spiral movement.

Hull.

NOTES ON A CASE OF CHRONIC ULCER OF THE STOMACH; EXCISION OF ULCER; POSTERIOR GASTRO-ENTEROSTOMY; CHOLECYSTOTOMY.

By W. McGREGOR YOUNG, M.A., M.D. GLASG.

Now that the operation of gastro-enterostomy has become so common the publication of a single case of the kind may seem uncalled for, although the case, even from the operative point of view, is not without its noteworthy features, but I have thought it might be of sufficient interest to bear reporting if, reversing the usual order of precedence, an account were given of what was found at the time of operation and the lesions present were compared with the signs and symptoms noted previously and the history of the case up to that time.

The patient, a man, aged 54 years, a sufferer from long-continued dyspepsia, had lost weight to the extent of two stones within the last year and showed on examination evidence of pyloric obstruction. An operation was advised after consultation with Mr A. W. Mayo Robson and Dr. A. G. Barrs and to this he consented. Accordingly, on Feb. 18th Mr. Mayo Robson operated, the patient having been on sterile food for two days beforehand and the mouth attended to with a view to oral asepsis. The stomach was found to be considerably dilated, the gall-bladder tense and full, and the tumour which had been imperfectly felt was a much enlarged and thickened pylorus. So hard and dense did this latter feel that it was impossible to say from sight or touch whether it consisted of new growth or not. In order to determine this Mr. Mayo Robson opened near the pylorus by an incision in the long axis of the stomach and exploring with the finger found it to be what it certainly did not look like from without, merely hypertrophy. A search was made further along the lesser curvature for the cause of this overgrowth and a very well marked and typical specimen of chronic ulcer was found on the posterior wall two and a half inches from the pylorus. The portion of stomach on which was the ulcer was clamped, the ulcer itself, of about the size of a sixpence with hardened edges and a bluish grey floor, was excised, and the mucous membrane was brought together by a continuous suture of green catgut. The incision in the wall of the stomach was stitched up vertically in the usual way with a double row of sutures, mucous and serous. Although the evident cause of the trouble had been discovered and removed it was thought wise lest other ulcers were present to perform a gastro-enterostomy. This proved, however, a matter of no little difficulty, for on attempting to reach the posterior wall of the stomach it was found that owing to an evidently long persisting perigastritis numerous adhesions had formed which prevented an easy exposure, the lesser peritoneal sac being obliterated and the transverse mesocolon firmly adherent to the stomach. A sufficient free surface of stomach for manipulative purposes was hard to find. A considerable amount of tension was consequently present after the junction of the jejunum and stomach was effected. There is little left of moment to relate; the patient made an excellent and uninterrupted recovery. It should, however, be added that the gall-bladder was emptied of its dark inspissated meconium-like bile, in which were innumerable tiny little gall-stones, and was drained in the ordinary way for two or three weeks.

---

[4] Hoffmann [illegible] ases of Bronchi and Lungs, p. [illegible].

I saw the patient the other day and he told me that his appetite and digestion were "simply marvellous"; he ate and drank anything not alone with impunity but with enjoyment. The patient had suffered for 20 or more years from dyspepsia, at first with intermissions of good digestion, but for the last two or three years almost constantly. Going back on his old symptoms—that is, prior to a year ago, so far as his memory could serve him—they come to this: heaviness, then epigastric pain, but not severe, shortly after a meal, continuing up to the next meal when relief came again for a time, belchings which sometimes gave him ease, regurgitations of sour mouthfuls and pyrosis, vomiting very rare, appetite good, and bowels constipated. These are evidently the symptoms of hyperchlorhydria and later chronic gastric catarrh

The lesions which showed themselves at the operation were an ulcer near the pylorus, which does not preclude the possibility of others being present elsewhere, great hypertrophy of the pyloric sphincter, a much dilated stomach, posterior perigastric adhesions, and a gall-bladder showing signs of biliary catarrh, full of inspissated bile and tiny gall-stones or grit. What part the latter played in his symptoms it is impossible to say, but at any rate I could elicit no story of attacks of biliary colic. How far, then, did the lesions found correspond to the symptoms complained of by the patient and the signs presented on examination?

1. *Pain*.—It was seldom severe, it was never intense, nor was it of a burning or sharp cutting kind, but rather there was present a sense of constriction and intense discomfort and distension; it began half an hour after a meal and increased during the next two hours It was felt first in the pit of the stomach and afterwards lower down but also across the chest and radiating to the shoulders. It was relieved completely by the next meal, so much so that for half an hour he thought he was going to escape in spite of all his past experience to the contrary. It was not made worse in the dorsal decubitus. These are not the symptoms one would expect from pyloric ulcer, but the posterior perigastric adhesions by hindering the motility of the organ may help to explain them.

2. *Hæmatemesis*.—He never vomited blood nor so far as he knew did he ever pass any by the bowel. This is against a diagnosis of ulcer.

3. *Vomiting*.—He very rarely vomited and only after attempting to take something heavier than usual. It was always a most painful process; the latter is not surprising in view of the adhesions, but in view of the dilatation one would have expected frequent vomiting.

4. *Belching*.—This was most troublesome and distressing too, in so far as it seldom brought much relief.

5. *Regurgitation*.—This was a constant sequel to every meal. It consisted of a greasy fluid with undigested bits of food.

These are quite in keeping with stagnation of food in a dilated stomach.

And now as regards signs.

1. *Tenderness*.—There was very little elicited anywhere, not at all over the pyloric end of the stomach. The only tender spot was over the greater curvature, its lower border, and to the right.

2 *Tumour*.—I think this was very doubtfully palpable at the pyloric end. Mr. Mayo Robson thought he could detect an enlargement there.

3. *Dilatation*.—This was thought likely from the obvious splashing three hours after a meal and was proved by distension with gas, the lower border extending from two and a half inches to three inches below the umbilicus.

4 *Peristalsis*.—This was very clearly seen as a well-marked wave along the whole length of the stomach and did more to convince the observer of pyloric obstruction than any other sign or symptom.

5. *Loss of weight*.—This was the most alarming symptom of all. He had lost two stones in weight in the last year. It was really this that made him come to me and it was this that made me urge the advisability of immediate surgical interference. It more than suggested malignancy but yet, as events proved the loss in weight was really the result of starvation. He had so reduced his rations in quantity and specially in nutritive value that he was literally starving himself, living as he did on beef-tea and gruel to escape pain, although not able to avoid discomfort. Obstinate constipation and a certain loss of strength and vigour may also be noticed. Lavage he bore badly, but a washing out of the stomach showed free hydrochloric acid.

To sum up, a diagnosis of ulcer of the stomach near the pylorus could evidently only have been made by deduction. The dilatation pointed to pyloric obstruction and the peristalsis made it fairly certain. As the obstruction was only partial and intermittent this was probably due to spasm. The most likely cause of this spasm was ulcer. So that, after all, one might have arrived at a correct diagnosis on general grounds, apart from such refinements as are implied in a chemical analysis after an Ewald's test breakfast of the contents of an Einhorn's stomach-bucket, although one would have to confess that many of the symptoms were of no help but rather a hindrance to such a conclusion.

Leeds.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PLEURO-PNEUMONIA ACCOMPANIED BY ABDOMINAL DISEASE.

BY PERCY ROSE, L.R.C.P. LOND.,
PRESIDENT OF THE PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.

THE patient was a healthy, well-nourished girl, five years of age, and was last at school on Feb. 2nd. Her mother had noticed that the child's face, legs, ankles, and body were becoming swollen and took her to a hospital on Feb. 5th, where she was examined, given a bottle of medicine, and told to come again in two weeks' time if she was no better. On the evening of the 9th local medical advice was sought as the "child seemed choking." She was then in bed and complained of pain over the lower half of the abdomen, which was tender on pressure; she called out frequently for the chamber utensil but passed nothing beyond a little flocculent stained mucus. There was considerable straining but no melæna. A lump was felt in the right iliac fossa. Her temperature was 98° F., her pulse was rapid, and her respirations were 50 per minute. The face was pale and the throat and the pharynx were normal. There were râles all over the front of the left chest and the resonance of both lungs was impaired posteriorly. A diagnosis of early intussusception was made and her removal to a hospital was advised. During the night the straining ceased and on the following morning the child's condition was lower. Her temperature was 98° and her pulse and respiration were respectively 180 and 80 per minute. At the hospital tubular breathing was noted at the left base and no intussusception was felt. The child died the same evening from pneumonia.

On the next day a post-mortem examination showed both lungs to be entirely solid and shrunken in appearance, and in many places, chiefly over the left apex, there was a layer of purulent lymph. On opening the abdomen no intussusception was apparent, but on removing and laying open the intestines the region of the ileo-cæcal valve was seen to be affected. For about one inch to one and a half inches on both sides of the valve there were recent crimson extravasations of blood in the submucous tissue, presenting flame-like patches half an inch in diameter. The lower inch of the ileum was œdematous and the crowded solitary glands were swollen and presented a sago-like appearance with a crimson background of extravasated blood. There were similar extravasations in the adjoining mesentery. The remainder of the intestine and other organs were normal The intestinal appearances were only compatible with the theory of a small intussusception which had slid back

The case presented several interesting features—namely, the preliminary general swelling the absence of serious symptoms four days before death (as was shown by the child s dismissal from the hospital for two weeks), the sub normal temperature, the pallor of the countenance and the post mortem appearances of the lungs and ileo cæcal region These all point to a pleuro pneumonia of excessive virulence and the virulence in my opinion was caused by the intestinal condition

Seven cases of pleuro pneumonic diseases simulating abdominal trouble were published in The Lancet[1] last year and the abdominal symptoms were explained on the theory of referred pain The present case might have been put under the same heading if the post mortem examination had not revealed a definite abdominal lesion It is noteworthy, however, that out of the seven cases two had sustained blows on the abdomen, one had non perforated gastric ulcer, another had a definite history of the same complaint and a fifth patient had been constipated for 12 days In the present case the abdominal trouble probably acted as a culture ground for pathogenic organisms which, when set free, aided and increased the virulence of the pleuro-pneumonia from which the child died, and the thought occurs that those seven reported cases of pleuro pneumonia may not merely have simulated but have been actually accompanied or preceded by abdominal disease

Canning town F

SEPTIC CONJUNCTIVITIS

By R W Doyne, M A Oxon, F R C S Eng,

READER IN OPHTHALMOLOGY IN THE UNIVERSITY OF OXFORD CONSULTING OPHTHALMIC SURGEON RADCLIFFE INFIRMARY SENIOR SURGEON, OXFORD EYE HOSPITAL AND ASSISTANT SURGEON ROYAL EYE HOSPITAL SOUTHWARK

From time to time among private patients of the better class one sees cases of acute inflammation of the conjunctiva with great thickening of that tissue and marked enlargement of the papillæ of both upper and lower lids, resembling somewhat in this respect, only more so a very acute follicular condition provoked by atropine, the inflammation is usually limited to the palpebral conjunctiva, but there is a tendency for it to pass round the fornices and to involve the ocular conjunctiva There is free lacrymation and the discharge is more serous than purulent Ptosis, more or less marked, is present There is generally tenderness or enlargement of the pre auricular glands and a good deal of constitutional disturbance is present The condition is generally limited to one eye Ophthalmic surgeons of experience will I think, at once recognise the affection I am attempting to describe, but those text-books that notice it are, as a rule, rather vague and some, I believe, classify the condition under acute trachoma, with which disease, however, it has hardly any thing in common It yields slowly but with certainty to nitrate of silver, sulphate of copper, or, better still, to argyrol (30 per cent) in the course of from three to eight weeks It is only when treated by hot fomentations, cocaine or tying the eye up (too often the case) that the affection becomes exaggerated and extends to the cornea, producing a "soppy" condition of that structure and sometimes small infiltrated ulcers towards its margin

I have for many years seen isolated cases of this form of conjunctivitis occurring so far as my memory serves me in the spring, summer, and autumn rather than in the winter My reason for drawing attention to it now is the fact that this summer, at any rate in the Oxford district there has been quite an epidemic of such cases In two days recently I have seen three severe instances quite unconnected with each other It would be interesting to know if this has been the experience of surgeons in other parts

The bacteriology of this affection should be interesting, it cannot be very contagious for with only ordinary pre cautions it is limited to one eye The train of symptoms suggest a septic origin and I have sometimes imagined I could trace a connexion with mangy dogs or cats but this is little more than speculation Perhaps others will be able to define a cause with more authority

ST GEORGE'S HOSPITAL

A CASE OF GANGRENOUS APPENDICITIS WITH PNEUMONIA AND EMPYEMA, THREE OPERATIONS, CONTINUOUS IRRIGATION OF THE PLEURAL CAVITY, RECOVERY

(Under the care of Mr H S Pendlebury)

For the notes of the case we are indebted to Dr A J Jex Blake house surgeon

The patient, a boy, aged 17 years, was admitted into St George's Hospital on Oct 21st, 1902, complaining of acute pain in the abdomen vomiting, and constipation The attack began very suddenly on Oct 17th, while the patient was working a carrier tricycle up hill, with severe pain in the lower part of the abdomen On the morning of the 18th he started work but he soon had to desist because of the violent pain and vomiting that ensued and he took to his bed The pain and vomiting continued on the 19th 20th, and 21st, and when he was admitted his temperature was 104 4° F, his pulse was 125, his respirations were 50, and his bowels had been confined since the 18th

On examination the abdomen was found to be quite rigid and board like, not moving at all on respiration There was no distension and marked tenderness in the right iliac region was present. Immediate operation was decided upon gas and ether were given, and Mr H S Pendlebury opened the abdomen in the right iliac region by an oblique incision three inches long The deeper layers of the abdominal wall were œdematous and as soon as the peritoneal cavity was opened a small quantity of thin, brown, puriform very offensive fluid welled up from it Considerable matting of the parts about the cæcum was observed and the appendix itself was not found, but about an inch above the cæcum a whitish gangrenous patch of the size of half a crown was seen on the outer aspect of the colon, with a corresponding gangrenous area on the abdominal wall in contact with it Further disturbance of the parts was deemed inadvisable, the cavity was packed with gauze and the lower three quarters of the wound were closed with fishing gut sutures and dressings of cyanide gauze and wool were applied The plug was removed under gas 48 hours later, the wound being dressed daily and the general condition of the patient showing considerable improvement His temperature was down to the normal on the 24th when a few of the stitches were taken out, and on the 28th the remaining stitches were removed On each of the latter dates several drachms of whitish inoffensive pus came away from the wound On the evening of the 29th the patient s breathing suddenly became embarrassed and he complained of acute pain over the right chest in front, there was no rigor but slight herpes was observed on the upper lip On examination there was dulness to percussion over the right base and axilla, with loss of vocal fremitus and breath sounds and a few sticky râles were heard, no friction sounds were detected The temperature ran up to 103 4° and on the next morning it reached 104 2° Dr W Ewart was called in consultation to the case and diagnosed empyema Aspiration was performed in the right posterior axillary line in the dull area but nothing more than a few drops of blood could be drawn off On the 31st the temperature was down to 100°, the pulse was 148 and the respirations were 48 and laboured Aspiration was [illegible] inch below and [illegible] creamy brown [illegible] next morning chloroform was administered and Mr Pendlebury resected one and a quarter inches of the fifth right rib just outside the nipple line, 25 ounces more pus escaped The empyema cavity was found to lie in between the lobes of the lung and consolidated lung tissue was felt behind it A large empyema tube (No 14) was inserted and the usual dressings were applied

---

[1] The Lancet, August 2nd (p 280) and 16th (p 440) 1902.

During the next eight days the temperature was 102° to 103° in the evening and not below 100° in the morning. A small amount of pus came daily from the abdominal wound and a few ounces of offensive blood-stained discharge issued from the empyema cavity. The patient's general condition remained fairly satisfactory and he perspired a great deal. During the night of Nov. 8th his temperature, taken twice under the tongue, fell from 102·4° to 95° and he became a little cyanosed and collapsed and vomited slightly three times. On the next day his aspect had improved considerably and his temperature was normal; his appetite was good, he was free from pain, and he had a slight cough with occasional expectoration of white frothy mucus. Three days later the sputum increased considerably, being pink in colour and typically pneumonic in consistency. On the 16th Dr. C. Slater, bacteriologist to St. George's Hospital, reported that the sputum contained "numerous organisms which are morphologically identical with the diplococcus pneumoniæ," and it retained its pneumonic character for the next 16 days.

Throughout the rest of the month of November and through December, 1902, and for the first half of January, 1903, the patient showed little sign of improvement; the empyema cavity remained open and able to hold over a pint of water and discharged a few ounces of pus daily; the abdominal wound refused to heal in its entirety and a sinus passing directly downwards for two and a half inches was formed. In the middle of December gas was given and the sinus was opened up and a few minute fæcal fragments were washed out from the bottom of it. At the end of December a system of continuous irrigation for the empyema cavity was set up at Dr Ewart's suggestion; a stream of boiled water at a temperature of 100° F. was run into the cavity at a depth of six inches from the surface of the chest through an indiarubber tube and was allowed to flow out again by a second tube from a depth of an inch. The rate of flow was regulated by a stopcock to about a gallon per hour; after the flow had continued for about half an hour the effluent was quite clear. The current was maintained usually for 24 hours at a time and caused little discomfort beyond an aching in the top of the chest and at the root of the neck on the right side; the pain was not diminished by the substitution of normal saline solution or boric lotion for the boiled water but was not sufficient, as a rule, to keep the patient awake at night. After a fortnight's trial the continuous irrigation was abandoned as it did not appear to benefit the patient materially.

On Jan. 9th Mr. Pendlebury opened up the appendicular sinus by a three-inch incision along the scar left by the operation of Oct. 21st and the appendix was found to be scarred and fixed by matted adhesions deep in the false pelvis, while there were also a number of adhesions about the cæcum. He removed the appendix, sewing a peritoneal sleeve over its stump, and closed the wound with fishing gut sutures All the stitches were out by the eleventh day and the wound healed satisfactorily. The empyema cavity continued to discharge a few ounces of pus daily and the patient's temperature was still raised at night; his general condition, however, improved and his weight increased from 6 stones 2 pounds on Dec. 17th to 7 stones on Feb. 11th, when he was sent to Atkinson Morley's Convalescent Home at Wimbledon for three months. At this time the upper part of the right lung showed some signs of re-expansion but the right chest wall had fallen in considerably and it showed marked deformity. During March and April the discharge from the empyema cavity grew less and less and finally ceased about the end of May, at which time the patient weighed 9 stones.

Remarks by Dr. EWART.—I was asked by Mr. Pendlebury to see the case at two critical stages—first on the second day of the acute symptoms, when the orthopnœa, the cyanotic flush, the profuse sweating, and the prostration were such that there seemed to be but slender hope, and again after many weeks when the prospect appeared to be one of progressive exhaustion. The patient's recovery from both dangers is no less remarkable than the ultimate complete re-expansion of his thorax.

1 The diagnosis of "latent empyema," to which I was led by the clinical history and the physical signs, was borne out by the character and the quantity of the pus which was pumped out of the chest two days later. The partial pneumothorax which was also diagnosed may be regarded as an explanation for the sudden accession of respiratory distress, in addition to the pneumonia identified by the pneumonic character of the expectoration which persisted for two weeks. It was obvious from the result of the first aspiration that the lung extended low down and that it must have been compressed as well as congested. The failure to reach the pus which was situated in front of the lower lobe might have led to the dulness being attributed entirely to pneumonia. As, however, aspiration had been practised only posteriorly the diagnosis of empyema was not abandoned but on the strength of it I recommended the anterior operation which proved successful.

2. Continuous irrigation with boiled water, the details of which were so skilfully carried out by Dr. A J. Jex-Blake, suggested itself to me as a method of treating an unhealthy empyema and a lung which I believed to be ulcerated, and of favouring the re-expansion of the thorax. The first of these objects was attained and I was impressed by the appearance of general improvement which I observed in the patient. But judged by the temperature chart, by the weighings, and by the patient's own report, the treatment could not be regarded as a success. Yet it did no harm and its cessation was followed by sufficient improvement to enable the patient to undergo the radical operation, after which the gradual drying up and the closure of the empyema were to be merely a matter of time.

Remarks by Mr. PENDLEBURY.—From the surgical point of view this case is distinctly of interest. First, it illustrates once again the fact that a large perityphlitic abscess may be formed without destroying the appendix, and I have little doubt that even if the abdominal wound had healed the boy would have had other attacks of appendicitis and would have had to undergo a subsequent operation for the removal of his appendix. It would probably have been yet another of those cases from a number of which Mr. W. H. Battle drew so many useful and valuable deductions. As it was, the persistence of a sinus obliged me to perform a second operation to remove the appendix. Secondly, as Dr. Ewart has pointed out, the operator should never be satisfied with aspirating the chest from behind only. After resecting a rib and examining the chest I was at once struck with the position of the abscess. I could feel compressed lung above and compressed lung below, and behind the great fissure being held open by the purulent material.

It is very difficult to say from such data as pulse, temperature, and respirations whether continuous irrigation was a positive help to recovery, but I have little doubt that it prevented a good deal of septic absorption by continually diluting and washing away the septic material. At any rate, the general condition of the patient improved.

In June I saw the patient after his return from the seaside. His weight had increased to over nine stones and the re-expansion of the chest was almost complete.

LIVERPOOL STANLEY HOSPITAL.

A CASE OF MEDIASTINO PERICARDITIS.

(Under the care of Dr. J. LLOYD ROBERTS.)

A BOY, aged five years, was sent into the Liverpool Stanley Hospital with general anasarca and was said to be suffering from Bright's disease. From his history he appears to have been a healthy child up to three months before admission, his only illness having been an attack of bronchitis when nine months old. About three months before his admission the patient began to lose his appetite, to stay indoors more, to be less inclined to play, and to become, as his mother said, "very quiet, which was an unusual thing for him." At this time it was also noticed that he was getting thinner. A medical man was consulted and he advised a course of cod liver oil but no improvement followed. Five weeks before admission the boy complained of abdominal pain and had diarrhœa and vomiting The pain ceased after a day or two but the diarrhœa and vomiting continued for some time. The mother noticed, also, that the boy's face began to swell and that his urine was diminishing in quantity. At that time the abdomen was not swollen but about a week later it was discovered to be so and his feet and legs also began to swell. Three weeks before admission an occasional cough came on and this had latterly become worse. The swelling of the legs and abdomen had gradually increased and the urine had continued to diminish.

On admission the patient, in spite of the history of wasting, was found to be a fairly well-nourished boy with well-marked anasarca all over the body. His face and eyelids were puffy. His hands, feet, and legs were swollen and œdematous. His scrotum and abdomen were distended. The temperature was subnormal, 97·2° F. His respirations were rapid and short, 34 to the minute. There was no dulness over any part of the lungs. Coarse râles and rhonchi were audible on inspiration and expiration over the whole of the chest, front and back. His pulse was small and regular, 82 per minute Cardiac dulness was increased slightly upwards and to the right. The cardiac sounds at the apex were normal; those at the base seemed somewhat faint. There were no bruits and no pericardial rub. The abdomen was distended and the umbilicus protruded. There was no tenderness. The liver dulness extended three and a half inches below the ribs in the nipple line. There was dulness on percussion in both flanks and a thrill was easily obtained There was considerable œdema of the abdominal walls. During the first 24 hours in the hospital the patient passed only two ounces of urine. This was high coloured, acid, deposited a large proportion of urates, and contained no albumin.

The diagnosis did not at first seem at all clear. The appearance of the patient with the puffiness of his face and the swelling of the legs and scrotum immediately suggested the correctness of the diagnosis of Bright's disease; but the condition of the urine, which was quite free from albumin and differed from the normal only in quantity, precluded that view. The slow, regular pulse with absence of cardiac murmurs negatived the suggestion of cardiac disease. The slight increase of cardiac dulness with feebleness of the cardiac sounds at the base suggested the possibility of pericardial effusion, but that in itself would not account for the patient's condition. It was clear that there was some serious obstruction to the boy's circulation and that obstruction could after a time be more or less accurately located. It was evidently above the junction of the hepatic veins with the inferior cava, as shown by the enlargement of the liver. Then the œdema of the face and hands showed that it also affected the superior cava. It appeared, therefore, that the obstruction was either in the right auricle or pressed against the auricle and kinked the inferior cava in its passage through the diaphragm. The absence of any bruit made the latter the more probable explanation. The patient lived only 13 days after admission. During this time, with occasional apparent improvement, the failure of circulation gradually increased and the boy became more and more water logged, the œdema being particularly marked in the abdominal walls and the lumbar region. During his stay he had a constant troublesome cough with respiration ranging from 28 to 48 per minute. The temperature was subnormal throughout except on the day of death, when it reached 100 8°. The pulse was regular, and varied between 82 and 120, being as often below 100 as over it In spite of the extreme backward pressure on the kidneys the urine throughout was extremely scanty, the average daily amount being only four and a half ounces, and only once was a trace of albumin found.

Necropsy —On removing the chest wall there was seen immediately behind it an irregular mass filling the anterior mediastinum. This was firmly adherent in front to the sternum and ribs and behind to the outer surface of the pericardium and the structures in the median line. The consistence was generally fibrous but in several parts the mass was caseating and in two or three places had actually broken down into thick caseous pus. The largest of these cavities was almost globular in shape, of about the size of a hazel nut, and had imbedded itself under the arch of the aorta. The mass also insinuated itself backwards, pressing against the right auricle, the vena cava superior, and the pulmonary veins, the obstruction of which vessels had produced all the symptoms noticed during life. Microscopically, thymus gland tissue was found in the mass and the inflammatory process appeared to have originated in the neighbourhood of that organ. The two layers of the pericardium were firmly adherent throughout and considerably thickened. The heart and its cavities were small and there was no evidence of endocarditis. The liver was very much enlarged and typically nutmeggy. The kidneys were congested but to the naked eye presented no pathological change There was no evidence of tubercle in the lungs or mediastinum

Remarks by Dr. LLOYD ROBERTS —This case presents a very fair instance of the typical signs of the acute form of mediastino-pericarditis as met with in children and illustrates the termination when the acuteness of the process leads to caseation and softening instead of the chronic indurative changes met with in the case of adults. The actual formation of pus, however, must be a rare occurrence, for although several cases of caseation have been reported in children in none of them is there any mention of further softening. One point of interest in the physical signs in this case was that the œdema of the abdominal wall was much greater in proportion to the amount of ascites than is usual in cases of anasarca from valvular disease. I have noticed the same thing in another case of intrathoracic obstruction and it occurs to me that it may be a point which might be of help at times in arriving at a correct diagnosis.

One other point. At the necropsy on my patient it appeared that it might have been a very feasible operation to trephine the sternum and to evacuate much of the caseating and breaking down material and thereby relieve the pressure on this boy's circulation. Should I meet with another case as acute as this I should certainly consider the propriety of surgical exploration.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Presidential Address.—Tumour of the Choroid in an Eye with old Choroiditis.—Tumour of the Choroid associated with Iritis.—An Anomalous Case of Tobacco Amblyopia.—The Pathological Anatomy of the Plaques in Epithelial Xerosis.

A MEETING of this society was held on Oct. 29th, Mr. J. TWEEDY, the President, being in the chair. The presidential address will be found in full at p. 1280.

Mr. E. NETTLESHIP described a case of Tumour in the Choroid in an Eye with old Choroiditis. A woman, 24 years of age, had lost the use of the right eye from inflammatory glaucoma. The eye was removed in 1894 and when last heard of six years later she was in good health The possibility of tubercle was indicated by a half-sister suffering at the age of 12 years from peritonitis and an abscess in the pubic region. Vision in the eye in question was defective at 15 years of age on account of detachment of the retina and secondary cataract. As it remained painful for from eight to ten years and a bulging behind the ciliary region with dilatation of vessels was observed the eye was removed. On examining the globe a staphyloma was found extending nearly from the attachment of the external rectus to the optic nerve, the corresponding portion of the choroid being occupied by an angiomatous sarcoma made up of round, oval, and spindle ween them wide blood olesterin-bearing stratum covering about a quarter of the surface. The optic nerve was atrophied and there were outlying nodules in the sclera. These features and the history suggested an origin in tubercle and hæmorrhage —Mr. PARSONS thought that such a case was almost unheard of. Fuchs described sarcomatous growths associated with cholesterin but they were of doubtful nature Leber cited cases of this association with shrunken globe and definite cyclitic changes. He thought himself that the condition resembled necrosis in a sarcomatous growth.

Mr. J. H FISHER described a case of Tumour of the Choroid associated with Iritis. A woman, aged 52 years, had her left eye excised on Oct. 5th, 1902 Six years before there were detachment of the retina and cataract apparently traceable to a blow The eye was blind and painful and the tension was raised. There was a small vascular spindle-celled growth near the entrance of the optic nerve with hæmorrhage and pigment showing signs of necrosis. A column of tumour cells could be traced along the tract of a ciliary nerve. Mr. Fisher described the lymph spaces and currents and the continuity of the two sides at the chiasma and suggested that sympathetic irritation might be due to transudation from the sound eye to supplement the nutrition of the injured one and cited several cases in support of this view.

Major F. O'KINEALY, I.M.S., described an anomalous case of Tobacco Amblyopia in a man, aged 42 years and single, who had had syphilis In August, 1900, he tried spectacles but his vision deteriorated and in September, 1901, it was greatly impaired. He had been a great smoker for nine years, accounting for 500 Burmah cheroots of a cheap and rank quality per month. With a reduction in the use of tobacco and alcohol and the use of strychnine he regained his sight and also weight which had diminished. Vision in each eye was reduced to $\frac{4}{60}$ and Jaeger 18 There were central defect in each eye and limitation of fields both for white light and colour with a large scotoma in the right eye and several smaller ones in the left. Tobacco and alcohol were cut off and strychnine and iron were given with pilocarpine. On Jan. 19th, 1902, vision was $\frac{6}{9}$ and Jaeger 1 in each eye with the aid of glasses, though the fields for white and red were still contracted and the multiple scotomata had run together into a complete ring, colour perception being still defective. Major O'Kinealy also cited another instance in a Eurasian from the same cause Vision was $\frac{6}{18}$ and Jaeger 18 in each eye with loss of fields for green and yellow, improving in two months to $\frac{6}{9}$ and Jaeger 1 with disappearance of scotoma and return of colour appreciation.—Mr W. LANG referred to a statement by Dr. V. H. W. Wingrave that he had observed a corresponding defect in hearing in tobacco-smokers suffering from amblyopia, which had improved with the vision on giving up smoking.—Mr. NETTLESHIP commented on the peculiarity in the reduction of the fields as vision improved —Mr. W. T. HOLMES SPICER asked whether syphilitic retinitis had not something to do with both cases.—Mr. JOHNSON TAYLOR combated the observation as to tobacco deafness; he had observed no such defect in his own cases.

Mr. M. S. MAYOU described the Pathological Anatomy of the Plaques in Epithelial Xerosis, which he attributed to the adhesion of a Meibomian bacillus resembling that in smegma, the presence of kerato-hyaline granules, and mucoid changes with keratinisation of the epithelium, citing six cases.—Major H. HERBERT said similar changes occurred in other mucous membranes. He had met with many characteristic instances where there appeared to be a tendency to desquamation of mucous membrane. The eye was first affected, then the larynx, causing a peculiar alteration in the voice; the urinary tract was also attacked as evidenced by the occurrence of large epithelial flakes in the urine. He attributed these bad cases of xerosis to an absence of mucous cells in the epithelial lining.

The following cases and card specimens were shown:—

Dr. G. H. GOLDSMITH: A case of Retinitis Proliferans.

Mr. W. ADAMS FROST: An Ophthalmoscope for Demonstrating the Fundus Oculi.

Mr. R W. DOYNE: A case of Varicose Retinal Veins with Thrombosis.

Mr. R. W. DOYNE and Mr. S STEPHENSON: A case of Retinitis Circinata.

Mr. W. H. H. JESSOP: A case of Proptosis.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Simulation of Hip Disease.—Ruptured Ovarian Cyst.—Personal and Family History of Patients —Exhibition of Cases and Specimens.

THE first meeting of the present session of this society was held on Oct 23rd, Mr. C. RICHARDSON, the President, being in the chair.

The PRESIDENT in his inaugural address referred to the importance of encouraging cheerfulness in many forms of illness and said that the medical attendant could not do this effectually if his own nerves were below par. In restoring jaded nerves nothing was so effectual as pleasing exercise in fresh air. Walking alone was not sufficient. It was wanting in the needful zest and apt to grow monotonous. He considered that golf was the pastime best adapted to the needs of the medical man and instanced the opinion of a leading American surgeon who said that "it was his duty to his patient that when operating he should be at his best and that his nerves could not be at their best unless he had regular doses of golf." Whatever the form of exercise it should be taken regularly and the pastime must be sufficiently entrancing entirely to lure the thoughts for the time being from the groove of the daily task. Whilst alcohol was not needed by the young and vigorous it might be useful to the weakly and those in the decline of life, if taken with care and discretion. He was strongly of opinion that usually it should be taken only with food and he gave a striking instance of the effect produced on the brain by a small quantity of alcohol taken on a perfectly empty stomach. Alcohol taken before exertion was detrimental, but afterwards in the stage of exhaustion by restoring equilibrium to the jaded nerves it tended to give comfort, cheerfulness, and health.

Mr. T. PRIDGIN TEALE read a paper on Disease of the Bursa over the Trochanter Major and its Simulation of Disease of the Hip.—The PRESIDENT, Dr. A. A. MCNAB, Mr. E. WARD, and Mr. E. TROTTER joined in the discussion and Mr. TEALE replied.

Dr. R. ALCOCK read a paper on Ruptured Ovarian Cyst followed ten months later by intra-abdominal sarcoma. The patient, who was 34 years of age, was suffering from abdominal enlargement when she received a blow from the handle of a washing machine in December, 1902; she was seized with pain and the abdomen increased rapidly to its utmost capacity. Laparotomy was performed on Dec. 21st at the Goole Cottage Hospital and the abdomen was found to be distended with thick slimy fluid exactly like the contents of an ovarian cyst. A cystoma of the left ovary was removed; it was an oval multicystic growth about 12 inches long and six or eight inches wide. Recovery from the operation was uneventful. Death took place from cachexia and vomiting on Oct. 3rd, 1903—i.e., little more than nine months after the ovariotomy. A partial post-mortem examination revealed the existence of a round-celled sarcoma of the peritoneum following the folds of the peritoneum and the omentum. There was likewise a sarcoma of the right ovary of about the size of a small orange. The appearances suggested that the peritoneum had become generally infected by the cystic fluid which escaped into the abdominal cavity in December, 1902 —Mr. WARD, Mr. B G. A. MOYNIHAN, and Dr. T. KILNER CLARKE took part in the discussion.

Dr. A. MANTLE read a paper on the Importance of a Thorough Investigation of the Patient's Personal and Family History in Disease. The personal history was important as to the kind of life which was lived, particularly in connexion with the amount of food and alcohol consumed and the occupation followed. A knowledge of previous illnesses was important but care should be taken in accepting the statements made by patients. The influence of season and temperature upon some patients was worthy of attention. Some patients were very subject to constrictive changes in the peripheral circulation through cold and practically felt well only in a warm temperature, whilst others showed symptoms pointing to capillary dilatation, such as exophthalmic goitre, erythromelalgia, and some other disturbances of the sympathetic, and a class including many fat people felt quite warm and comfortable in the colder weather. The family history enhanced the value of the personal history. Some families were short-lived, their tissues degenerating early. Inheritance played a most important rôle in the resisting power and longevity of the cells constituting tissues and nothing showed the law of transmission more than that highly specialised tissue the grey matter of the brain and spinal cord. Neurotics ought to be dissuaded from marrying neurotics and consumptives from marrying at all.

Mr. G. CONSTABLE HAYES showed cases to illustrate the Action of Radium and Radiographs to show the Advantages of the X Rays for the purpose of Diagnosis.

Other cases and specimens were shown by Mr. WARD, Dr. A. G BARRS, Dr. J. B HELLIER, Dr. T. WARDROP GRIFFITH, Mr. HARRY LITTLEWOOD, Mr. WALTER THOMPSON, Dr. E. F. TREVELYAN, and Mr. R. LAWFORD KNAGGS.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held at the London Institution on Oct. 28th, Dr. F. J Smith being in the chair.—Dr. J. H. Sequeira showed four patients suffering from various Syphilides. One of them was a girl, aged 16 years, whose nose, upper lip, and palate had been the seat of gummatous ulceration. Comment was made upon the rarity of tertiary ulceration in congenital syphilis. The patient had been treated at a hospital as a case of lupus and the parts had been scraped with disastrous results. There was distinct evidence of congenital syphilis in one upper incisor tooth. The ulcers had healed in a month with iodide of potassium and mercury taken internally and iodoform applied locally.—Dr. T. Glover Lyon in reference to this case said that he thought that the syphilis was acquired.—Dr. Sequeira, in reply, pointed out that the first manifestations occurred at the age of 13 years and that there was an undoubted Hutchinson tooth —Dr J [illegible] enlargement of the cervical, axillary, and inguinal glands, there were no pain or tenderness and little, if any, pericarditis The spleen could not be felt, the liver was a little enlarged, but the other organs appeared healthy The blood count showed 2 500 000 red corpuscles and 250,000 white cells per cubic millimetre, 97 per cent of the hugely increased white corpuscles were lymphocytes A great improvement was made under treatment with large doses of arsenic —Dr Bertrand Dawson showed a woman suffering from Syphilitic Perihepatitis which had produced a large tongue shaped Riedel's lobe She had had many miscarriages She had greatly improved under potassium iodide At one time there had been definite localised peritonitis around the liver Dr Dawson could not entirely exclude malignant disease of the liver because of the great number and hardness of the nodules on it but the patient's good general health did not support this view —Dr Smith said that the case seemed to him to be one of intermittent hydronephrosis because great variations in the tumour were reported to be associated with variations in the urine —Dr Le Rossignol said, however, that actual measurement of the urine did not confirm the patient's account —Dr Dawson then showed a woman with an undoubted Riedel's Lobe of the Liver probably due to tight corsets —Mr Barnard pointed out that if Riedel's lobe were taken to mean a tongue shaped process projecting downwards from the lower border of the right lobe of the liver then there were three varieties (1) that due to corsets, (2) that due to enlargement of the gall bladder, and (3) that due to syphilitic perihepatitis and scarring of the liver The cases shown by Dr Dawson illustrated two of these varieties —Dr Smith showed a man, aged 51 years who 27 years ago met with an accident to one testicle, after which an abscess formed there, this had healed at last, leaving hard lumps in the testicle and cord There was now a lump in the right side of the abdomen which was undoubtedly the right kidney, probably considerably enlarged and tuberculous —Dr W H Kelson showed a woman, aged 38 years, the posterior pillars of whose fauces were adherent to the pharyngeal wall and to each other in the middle line The condition was believed to be due to a severe attack of scarlet fever when a child The patient suffered very little inconvenience and was unaware of the presence of anything abnormal

THERAPEUTICAL SOCIETY — The first annual meeting of this society was held at the Apothecaries Hall on Oct 27th Sir William Thiselton Dyer being in the chair —The following officers were elected for the ensuing year President Sir William Thiselton Dyer Vice President Dr J Rose Bradford Treasurer Dr S C Griffith Secretary Dr T E B Brown Dr J H Bryant was elected on the council and Mr Peyton Beale Mr E Dennis Vinrace and Mr Chattaway were confirmed on the council, having been elected to fill vacancies —Dr Harrington Sainsbury then read a paper on the Action of Bodies in the Particulate State with special reference to the action of carbon, of which the following is an abstract The importance of the physical state of aggregation as a factor in the action of medicines upon the tissues was shown Given an affinity between the substance and the tissues the dependence of the reaction was upon (1) the vibration rate of the particles, (2) the density or molecular crowding, and (3) the extent of surface presented by the substance The three states of matter—solid, liquid, and gaseous—were contrasted in respect of these qualities, the conclusion being arrived at that the liquid state was the most active and that the solid state (in proportion to the insolubility of the substance) was the least active The action of solid bodies on the tissues was analysed according as the substance was (1) soluble but undecomposable, (2) insoluble but in part decomposable into a soluble substance, and (3) wholly insoluble and wholly unchangeable Carbon was a type of Class (3) Its mode of action by virtue of its mechanical action and by virtue also of its powers as an absorbent was considered, the conclusion being arrived at that neither of these explains the effect produced by carbon Details of experiments in evidence of the small part played by absorption were given and it was concluded that the action of carbon must depend principally upon a peculiar surface action as yet un- [illegible] for his very [illegible] lar action of [illegible] chlorophyll on the gases which form the food of plants —Dr Ince seconded the vote of thanks to Dr Sainsbury and also proposed a vote of thanks to the President. This was unanimously agreed to —After the paper Mr Chattaway showed a splendid specimen of Radium and narrated Some Experiments with X Rays and High Frequency Currents —Mr Bryant Sowerby of the Regent's Park Botanical Gardens exhibited some interesting specimens of Chinese Medicinal Teas as well as of Drugs and Medicinal Plants

MIDLAND MEDICAL SOCIETY —The annual meeting of this society was held at the Medical Institute in Birmingham on Oct 21st, Dr H W. Langley Browne, the President, being in the chair —On the reports of the council and the treasurer being received, the following officers were elected for the ensuing session President, Dr. Robert Saundby, treasurer, Mr John Garner, and honorary secretaries, Dr J Douglas Stanley and Mr Leonard P Gamgee —At the conclusion of the general meeting the first ordinary meeting of the session was held —Dr Stanley showed a specimen of Cardiac Aneurysm The patient was a woman, aged 72 years, who was admitted under his care at Queen's Hospital, Birmingham The cardiac impulse was in the fifth and sixth left intercostal spaces and outside the mid-clavicular line, it was weak and fluttering in character The first sound was muffled and the pulse was irregular and feeble The vessels were degenerated The patient suffered from increasing œdema and ascites appeared The irregularity of the cardiac action became more marked and although a murmur developed in connexion with the first sound there was a want of proportion between this feature and the very serious condition of the heart. There was slight albuminuria, the specific gravity of the urine being low The diagnosis was progressive cardiac dilatation due to chronic myocarditis Death occurred from cardiac failure On post mortem examination the heart showed a well marked bulging to the left with a localised pericardial adhesion Closer examination revealed a well marked aneurysm of the left ventricular wall in which was a large mass of clot The ventricle at this point was much thinned There was marked chronic myocarditis of the whole ventricular structure, the coronary vessels showed slight degeneration The diffuse myocarditis was confirmed microscopically Dr Stanley considered that the cause of the aneurysm was myocarditis, the pericardial adhesion being secondary and mechanical —Mr J F G Pietersen read an interesting and instructive paper on the Medical Certification of the Insane He described cases of difficulty and the best methods of dealing with them from the legal as well as from the medical point of view He strongly emphasised the great importance of asylum treatment for all cases of mental disease —The paper was discussed by several members

BRADFORD MEDICO CHIRURGICAL SOCIETY —The annual dinner of this society was held on Oct 13th, Dr H Angus the President elect being in the chair About 70 members and guests were present Previously to the dinner an address was given by Mr Rickman J Godlee on Some Conditions leading to Chronic Septic Absorption —The first meeting of the present session was held on Oct 20th, Dr Angus, the President, being in the chair —The President delivered his opening address, the subject selected being Types of Dyspepsia. In summarising his conclusions he said that dyspepsia was essentially due to functional derangement of the nervous system In dietetic treatment fats were to be avoided when the gastric secretion was already deficient, but the more digestible forms of fat were indicated in cases where secretion was excessive Animal proteids were more digestible than vegetable proteids but much depended on the stage of gastric digestion which had been reached at the time when different foods were taken —Mr J T Crowe showed a case of Pott's Disease of the Spine with Paraplegia which had been treated by costo transversectomy The case had been operated on by Dr W H Brook of Lincoln. The patient was a lad, aged 19 years, who had a well marked angular curvature in the dorsal region After treatment for a considerable time with plastic jackets he rapidly lost the power of walking and finally of sensation in the lower limbs The sphincters were affected The knee jerks were present. The operation was described in detail. The patient was now able to walk well and had recovered sensation. He was wearing a steel spinal support. —Mr. W. H. Horrocks read notes on a case of Pregnancy complicated by Uterine Fibroids which he had treated by abdominal hysterectomy. In performing the operation Mr. Horrocks had ligatured one uterine artery and had put a ligature around the other before incising the uterus. As soon as the child was delivered the ligature around the second uterine artery was tightened and there was practically no loss of blood. The child was alive and the mother made a good recovery.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 28th, Dr. J. Nigel Stark, the President, being in the chair.—Dr. Parry demonstrated a Tumour of the Ovary which was composed of myomatous tissue and was exceptionally large. He also showed a Tuberculous Salpingitis the removal of which necessitated the resection of the piece of intestine adherent. Part of the cæcum and a second piece of small intestine had also to be resected. The patient did well. Sections of the diseased tube were exhibited.—Dr. Russell showed, for Dr. Edgar, a Myoma of the Ovary and a Tumour of the upper part of the Rectum and Sigmoid Flexure, also a Fibroid Uterus complicated by Carcinoma of the Cervix —Dr. Teacher showed, for Dr. Christie, a simple Papilloma of the Nipple. The patient was 34 years old. The rarity of such growths was remarked upon.—Dr. Russell showed, for Dr. Kelly, a seven months Fœtus from an Extra-uterine Pregnancy. The history of this case was as follows. There were symptoms of ordinary pregnancy. At the end of the third month the patient had an attack of severe pain, sickness, &c. This attack was repeated in two weeks and again in two months, when fœtal movements ceased. The fœtus was partly macerated and the placenta was degenerated. An Unruptured Tubal Pregnancy of the Fourth Week was next exhibited. A minute embryo was found in the amniotic cavity. Sections of a Primary Carcinoma of the Ovary with secondary involvement of the tube and peritoneum were shown.—Dr. Teacher gave a lantern demonstration of Chorion Epithelioma and Allied Conditions.—A series of Instruments, principally modifications of the Bossi dilator, were exhibited.

EDINBURGH ROYAL MEDICAL SOCIETY.—A meeting of this society was held on Oct. 30th, Dr. P. F. Shaw, the senior President, being in the chair.—Dr. Low read notes on a case of Addison's Disease without Pigmentation. The patient complained of numbness of the feet and swelling of the hands and face. His cerebration was slow, his skin was harsh, coarse, and dry, his temperament was melancholic, and his circulation was extremely feeble. He had also gastro-intestinal trouble. The case was diagnosed as one of myxœdema and thyroid feeding was used. Under this treatment he improved for a few days but symptoms of thyroidism supervened and it had to be stopped. The patient then got gradually weaker and the case terminated fatally by heart failure. The necropsy showed fatty degeneration of the heart and the liver. The right suprarenal capsule was absent and the left one was greatly atrophied. The peculiarity of the case was that there was no pigmentation.—Dr. Dunbar read notes on a case of Spleno-medullary Leucocythæmia. The patient was a middle-aged woman and her chief complaint was weakness. There was very marked leucocytosis, the increase being most marked in the polymorphonuclears and in the myelocytes. She was treated with arsenic and after several months' treatment in hospital was discharged greatly improved —Dr. Campbell read notes on a case of Hysterical Ischuria. The patient was a young woman and her case was very like one of acute Bright's disease. The amount of urine passed by her daily was very small but she had no symptoms of uræmia. The daily excretion of urea was likewise very greatly diminished. She had numerous stigmata of hysteria.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—A meeting of this society was held on Oct. 28th —Mr. James Clark read a paper entitled "Gynæcological" He discussed at length puberty and the climacteric period. The ovaries were the chief factor in the changes associated with puberty, as was shown by the case of a child, aged 15 months, who had hair on the mons Veneris, menses, and an abdominal swelling; removal of the ovaries led to the patient regaining the normal appearance of a child of that age.—Mr. A. D. Pringle read a paper on Internal Derangements of the Knee-joint. In miners and football and tennis players displacement of the semilunar cartilages (most often the internal) frequently resulted from prolonged flexion and then sudden extension, or from flexion followed by a simultaneous twist and extension in the two latter cases. Pieces of thickened synovial membrane were sometimes snipped off by the membrane getting caught between the bones. Treatment for displacement was manipulative, instrumental, or operative, the last being the best. Strong antiseptics should not be used. Sterile normal salt solution was the safest. The finger should not be introduced into the opened knee-joint if possible. They could not always observe this rule as foreign bodies frequently got stuck about the crucial ligaments.

NEWPORT MEDICAL SOCIETY.—A meeting of this society was held in the board room of the Newport and Monmouthshire Hospital on Oct. 28th. The following clinical cases, specimens, &c, were exhibited and discussed: (1) A case of Lupus under Treatment by Roentgen Rays; (2) Knee-joint with Effusion, the result of gonorrhœa; (3) a Calculus removed by Suprapubic Cystotomy; and (4) Photographs and Roentgen-ray Pictures of a case of Carcinoma of the Clavicle. —Mr. J. Lynn Thomas, C.B, read a paper on Prostatectomy, giving his experience in cases on which he had operated by Freyer's method.

Reviews and Notices of Books

The Alien Immigrant. By Major W. EVANS GORDON, M.P. (late a member of the Royal Commission on Alien Immigration). With map and numerous illustrations from photographs by the Author. London: William Heinemann. New York: Charles Scribner's Sons. 1903. Pp. 323. Price 6s. net.

THIS book, which deals with a matter of great difficulty and complexity, is an honest attempt to bring before the public both aspects of a question which has been the subject of prolonged and bitter controversy. Major Evans-Gordon has made the question of the Hebrew migration to the West peculiarly his own and the book is the outcome of a long continued inspection of the conditions of the aliens in the East-end of London, of painstaking inquiry during a journey in Eastern Europe undertaken when Parliament rose in the summer of 1902, and of the part he took as a member of the Royal Commission on Alien Immigration. The majority of the alien immigrants whom this country receives are the homeless poor of Eastern Europe—Jews who leave their countries in consequence of some form of persecution or from the knowledge of the inferior position they occupy and with the hope that their descendants may be both educated and free Although Major Evans-Gordon states in his preface that his object is to put both aspects of the case before the public as impartially as he can, yet a study of the work shows us that the weight of his experience is altogether thrown into the balance which urges immediate legislation. While he is scrupulously fair in his treatment of the Jewish population, yet, taking into consideration that trades and occupations are overstocked, he thinks it right to press on the attention of the public that these worthy descendants of Jacob are supplanters and that the Christian fares as the Canaanite fared. "He is expropriated." The Jews are, as he says, a race apart and he lays stress on the evil which must result from the rapid inflow of a population accustomed to ignore sanitary requirements and to overcrowd, both of which evils are aggravated by the abiding separatism of the race.

The possibility of legislation becoming necessary was considered by the House of Commons in 1889 but the author points out that the problem both as regards the number of aliens and the area affected is now beyond all comparison graver and more urgent than it was 14 years ago The necessity for action cannot be more forcibly illustrated than by the extract from the report of the Jewish board of guardians for 1901 and by the figures published by the Board of Trade which the author quotes. The figures show that, leaving out the year 1901, the immigration of Russian Poles and Roumanians has increased nearly 400 per cent. and the increase which caused so much anxiety to the Jewish community in 1900 was surpassed in 1902 by 3074, the total amounting to 21,013 The tide of ill-considered immigration therefore continues and is steadily increasing in volume. The author repeats Dr. Herzl's warning to us in London "that we are not at the end but at the beginning of the Jewish immigration" and quotes the authority of the Bishop of Stepney who says that East London is growing more and more poverty-stricken.

The author points out that the immigration now taking place is vitally distinct from the coming of the Huguenots and other Protestants who became merged in the population. The Hebrew people form a colony permanently distinct—"a race apart, as it were, in an enduring island of extraneous thought and custom." Including the children born of foreign parents living in this country he estimates the number of aliens in the East-end to day to be not less than 88,000 East of Aldgate is practically a foreign town where in the streets it is an exception to hear the English language spoken, while in hundreds of houses a single room serves as workshop, kitchen, bedroom, and living-room, and no matter at what hour of day or night the passer-by hears the machines and through the windows, by the light of a dim lamp, sees the victims of the sweaters, imported from Vilna or Lodz, bending over their work. The aliens in the East-end have already taken up the most varied avocations. The author says it is not an exaggerated forecast to say that every considerable commercial centre in England will be confronted with the problem of congestion, sweating, and "the aloofness of Israel" if the present conditions of free and unregulated immigration continue.

During his tour Major Evans-Gordon passed from St. Petersburg to Dvinsk in the Jewish pale, thence to Riga, Libau, Vilna, Pinsk, Warsaw, Lodz, Cracow, Bucharest, Galatz, and, returning *viâ* Lemberg in Galicia to Berlin, ended his journey at Hamburg. At Vilna he saw the Jewish Ghetto in all its original picturesque squalor but he says he observed little in Vilna more horrible than he has seen in Whitechapel. It is not necessary to visit Russia to see the horrors of the Ghetto—they are here in our midst, daily increasing, the just reward of an inert public.

In the main the emigration to England comes from the lowest stratum of the Jewish society in the congested towns. From Poland the emigrants to England are, as a rule, drawn from the most necessitous class and from Roumania from the poor and incapable. The law requires everyone to obtain permission before leaving Russia; the procedure is complicated and expensive but there is the alternative for the outgoing traveller to get himself smuggled across the frontier. By the latter means all persons absconding from justice, deserters from the army, and others escape and it is clear that the undesirables and criminals of whom we have so much complaint in London come chiefly by this route. Of the other aliens who come to our shores from different countries many are merchants and skilled craftsmen whom no sane person proposes to impede but concurrently there proceeds a systematic incursion of criminals and vicious persons for purposes of criminality and vice. The cost of maintaining these alien criminals is a serious burden on the community.

We have quoted enough of Major Evans-Gordon's book to show its worth. The sooner Parliament frames laws to prohibit the landing of these undesirables the better. The recommendations of the Royal Commission of 1902 are before the public and show that every European country exercises the right to expel and to shut out criminal and disorderly persons and paupers. We have, moreover, before us the remarkable fact that where their own colonies are concerned (the Hirsch Jewish settlements in Argentina) the Jewish authorities take the most elaborate precautions to prevent the very evils from which we are suffering in the East end of London.

On his return journey, at Hamburg, Major Evans-Gordon studied the admirable and efficient machinery by which undesirable emigrants are sifted from among those *en route* to the United States of America. He describes the system and points out that if restrictive legislation were placed on our Statute Book all emigrants embarking at that port would immediately come under similar control—a control which would not throw a penny of expense upon this country. The danger of infection induced the American people to regulate immigration by law but more recent legislation has been based on economic and social, not upon directly hygienic, considerations and is firmly supported by the American Jews themselves The question of alien immigration is one which no Government ought longer to neglect for the evils are known to, and are appreciated by, all thinking men. It is to be hoped that this book will have the large circulation which it deserves and will bring home to the masses the absolute necessity of demanding from the candidates who solicit support at the next general election a promise to promote legislation in this direction.

A Pocket Guide to Anæsthetics for the Student and General Practitioner. By THOMAS D. LUKE, M.B. R.U.I., F.R.C.S. Edin. Edinburgh: W. Green and Sons. 1902. Pp 148

THE book before us contains nine chapters and an appendix and gives the usual information required by students concerning the apparatus and methods necessary for the production of anæsthesia. The apparatus, besides being mentioned in the sections dealing with nitrous oxide gas, ether, and chloroform, is also dealt with in a special chapter. For nitrous oxide gas the older methods of giving gas are described but not in detail and the many difficulties besetting the path of the beginner do not find any particular mention in the book. Although the gas-to-ether combination is described it does not appear that Mr. Luke habitually employs it as he treats of ether very fully and leads the reader to assume that the student will confine himself to the plan of commencing the inhalation straightway with ether. While upon the subject of mixtures and successions of anæsthetics we may say that we find occasional mention of the employment of the A.C.E. mixture and mixtures in which the alcohol is omitted but the book gives no very precise directions as to how they should be used and controlled. It is true that the suggestion of Lawson Tait to employ a small Clover's regulator without the reserve bag is mentioned. Ether itself finds favour with Mr. Luke. Ether bronchitis he has never seen, nor, according to him, has Mr. Teale met with more than one case during 20 years of practice. Mr. Luke adds: "The proportion of patients suffering from true ether bronchitis is infinitesimal," and referring to the occurrence of post-ether albuminuria he states: "There is little doubt, however, that there was pre-existing renal disease, and that neither chloroform nor ether have the power of producing the most transient albuminuria." With regard to this last statement we were under the impression that both the evidence of experiment and of clinical observation went to prove that while ether does in a certain number of cases induce transitory albuminuria unimportant in normal subjects, chloroform superinduced albuminuria only when the kidneys were diseased and when it did so often severely taxed the vitality of the nephritic structures. It is certainly not at present clear what is the exact pathological meaning of derangement of the kidney following severe surgical procedure under anæsthesia—how much is owing to the surgical shock and how much to the anæsthetic. With regard to chloroform, quoting Syme's rule to "Watch the breathing," Mr. Luke says: "While I should be sorry if at the present day we had to rely on nothing but this, still too much importance cannot be attached to it." He adds: "One must judge of the condition of the patient from no single sign but from the breathing, condition of pupil, colour of lips, amount of chloroform given, the type of the patient, and nature of operation." Although, speaking generally, the last quotation probably represents the mental condition of the expert we venture to think that the tyro who rivets his attention upon the respiration is less likely to go astray than if he aspires to a wider range of observation. Apparatus for chloroform giving is not insisted upon, although a Schimmelbusch's mask with a drop-bottle finds favour. It might, we think, be emphasised that every administrator of any anæsthetic should be provided with a set of instruments for the performance of laryngotomy or tracheotomy, since emergencies do arise even in the hands of the most skilled anæsthetist which renders this precaution necessary. There is not much said in the book about such emergencies; probably an addition dealing with them would be useful and might replace some redundancies and unnecessary pages, such as Chapters I. and IX., the subject-matter of which could quite well be comprised in a couple of paragraphs. Eucaine-β and some other local anæsthetics are described and the methods of Schleich's and Bier's lumbar puncture are given with a very proper caution about the obvious perils of subarachnoid cocainisation. The chloride of ethyl employed for local and general anæsthesia is mentioned but we should judge fails to gain the favour of the writer of this book.

Chemistry, General, Medical, and Pharmaceutical, including the Chemistry of the British Pharmacopœia By JOHN ATTFIELD, F.R.S, Ph. D. Edited by LEONARD DOBBIN, Ph D., F.I.C., F.C.S. Eighteenth edition. London: Gurney and Jackson. 1903. Pp 856. Price 15*s.*

MANY chemical students, but pharmacists in particular, will welcome this eighteenth edition of the work of Dr. Attfield who was for 34 years teacher of practical chemistry to the Pharmaceutical Society of Great Britain. With pharmacists it is quite a historic manual and there is no need to speak of its great popularity, seeing the number of editions that have been demanded. The success of this book has been due to the fact that its writer was perfectly familiar with the requirements of the class of reader for which it was specially written. Nor was this done at the expense of general principles. The book is at the same time a work of theoretical and practical chemistry, and the latter section includes analytical processes directed more or less to the examination of drugs. A glance at the admirably compiled index gives some idea of the skill which the author has shown in dealing with a very broad subject within the limits of this volume. Thus the elements of organic as well as inorganic chemistry are dealt with, a plan for the systematic examination of metallic salts is given, theory and nomenclature are discussed, alkaloids and their reactions are described, and methods for the analysis of blood, milk, and urine are given, besides a number of methods for the quantitative determination of metals and their acid radicles. Dr. Attfield has been fortunate in obtaining the collaboration of Dr. Leonard Dobbin in the preparation of this edition and we find, as might have been expected, considering Dr. Dobbin's special experience of the general application of chemical science to medicine and pharmacy, hat the manual in its present revised form is in accord with the recent developments of the science. Like Dr. Attfield he is cognisant of the needs of the class of reader for which the book was primarily intended. The plan of the book is admirably conceived, the facts and principles are well arranged, while the extraordinary scope of the work, dealt with as it is in one volume, is a matter upon which both author and editor may be heartily congratulated.

Bacteriology: a Manual for Students and Practitioners. By FRED C. ZAPFFE, M.D., Professor of Pathology and Bacteriology in the Illinois Medical College; Professor of Histology in the Department of Medicine in the School of Dentistry in the University of Illinois, Chicago Kimpton's Series of Modern Text-books edited by BERN. B. GALLAUDET, M.D. Illustrated with 146 Engravings and seven Coloured Plates. London: Henry Kimpton. 1903 Pp. 350. Price 7*s.* 6*d.* net.

THIS work forms one of a series of modern text books issued by Mr. Kimpton. With the present plethora of text-books of bacteriology it is natural to the reviewer to examine whether in any new book the author addresses a special class of readers or claims any originality of treatment. Apparently in this case the book is intended for the student and the general practitioner and the author modestly claims that it enables the beginner to gain a full and comprehensive view not only of the subject itself but also of its practical relation to medicine. The book is divided into four parts, of which the first and the third are the most important. The first part treats of the technique of bacteriology and is based on a series of laboratory directions used by the author in his practical course. The third part, which appears to us to be the best, is a description of the various pathogenic bacteria in which especial stress is laid upon such points as are of clinical importance. Based as the technical part is on a practical course, we are surprised that so much stress is laid on the difficulties of making nutrient agar, as since the introduction of the autoclave they have almost ceased to exist, and astonished to find that articles for sterilisation are to be placed in the hot-air steriliser *after* the temperature has reached 150° C. Nor is there usually any difficulty, with English lenses at any rate, in examining a hanging-drop culture with an oil immersion objective. The terms "superheated steam" and "steam under pressure" are used as synonymous but to the English student at least this is misleading and it is the more important as superheated steam has not the disinfectant value of saturated steam under pressure The student is likely also to be puzzled by the statement that chlorinated lime is used for the preparation of milk of lime and he will find some difficulty in making an intravenous injection in an animal if he acts on the instructions given. The portion of the book dealing with the pathogenic organisms is, on the whole, satisfactory, the needs of the practical physician being kept steadily in view. It seems, however, a grave fault in a text-book to speak of Coley's fluid and the typhoid "vaccine" as sera, since the student is naturally very prone to confuse these fundamentally different bodies. Unfortunately, throughout the book there are other evidences of haste which detract from its value and which should be corrected in another edition. Thus it is said that diabetes and tuberculosis are rarely found associated and we meet with the cryptic utterance that "it is strongly suspected that the lysins are the same as the agglutinins, although by no means identical." The volume contains a large number of illustrations derived from various sources, most of which are well produced, while the paper, printing, and general style of the book are satisfactory.

JOURNALS AND MAGAZINES.

Annals of Ophthalmology. Edited by H. V. WURDEMANN, M.D. July, 1903. Vol. XII., No. 3. Subscription for four quarterly parts, £1 1*s.* St Louis, Missouri, U.S.A.: Jones H. Parker.—The articles contained in this part are: 1. The

Accommodative Asthenopia of Donders, by George J. Bull, M.D. The author considers that the cause of accommodative asthenopia is to be sought for in irregular and disordered tension of the motor muscles of the eye and not in the ciliary muscle, and he considers that rest and treatment of the general health with the temporary use of glasses will generally suffice to relieve the state of hypertension of which the patients complain and that whilst in certain cases glasses must be always used, in others an operation regulating the relation between accommodation and convergence must be relied upon to effect a radical cure. 2. Why not employ Intracapsular Irrigation in Cataract Operations? by H. O. Reik, M.D. The answer given is favourable to irrigation but Dr. Reik considers that the aseptic fluid injected should be abundant, amounting in some cases to as much as 200 cubic centimetres, and that all the residue of the lens after the removal of the cataract should be expelled. 3. A case of Tuberculosis of the Conjunctiva, by F. Q. Henderson, M.D. In this case recovery took place without interference. 4 Papillomata of the Conjunctiva and Cornea, by R H. Johnston, M.D. 5. A Clinical Lecture on the Art of extracting for Cataract, by C. Bell Taylor, M.D. 6. Clinical and Histological Report of a case of Purulent Metastatic Ophthalmia in Meningitis giving rise to Meningitis and Sympathetic Symptoms after 13 Years, by C. Zimmerman, M.D., and Brown Pusey, M.D 7. Abstracts of *Foreign Ophthalmological Literature*, by Charles Oliver, M.D., and Clarence Van Epps, M.D.

Analytical Records

FROM

THE LANCET LABORATORY.

LYSOFORM (A NEW ANTISEPTIC) AND ITS PREPARATIONS.

(The British Lysoform Syndicate, 56, Cannon-street, London, E C)

THOUGH it has been said that the ideal antiseptic has not yet been found it would appear that lysoform is largely in advance of the bulk of antiseptic preparations considering the facts that it is not only a very powerful germicide but is also for all practical purposes non-poisonous. Moreover, as our experiments have shown us, it is an effective deodorant. It is specially adapted for medical purposes because in the first place it is freely soluble in water in all proportions and in the second it possesses decided detergent properties also. Lysoform, in fact, may be regarded as a liquid antiseptic soap. It is non-irritating and presents, in general, properties which are not harmful to the higher animals. Its germicidal efficiency has been established by several well-known bacteriologists. A 5 per cent. solution of lysoform is fatal to such organisms as the typhoid bacillus, the bacillus coli, and the staphylococcus pyogenes aureus, and a 3 per cent. solution will destroy the highly resistant spores of anthrax within 24 hours. These results are scarcely surprising having regard to the fact that the basis of lysoform is the powerful antiseptic formaldehyde. For antiseptic purposes and in medical application there are, however, several well-grounded objections to the employment of formaldehyde in the pure state, the chief of which is that *it is very irritating to the skin and* to the mucous membrane. Lysoform, on the contrary, although containing formaldehyde, has no such irritating action when employed diluted though still at an efficient germicidal strength. The merit, in fact, of lysoform is that whilst presenting all the antiseptic advantages of formaldehyde it is without the drawbacks of that agent in the pure state. According to our analysis lysoform consists of a potash soap containing a definite amount of formaldehyde and a small percentage of alcohol. It is a lemon-coloured solution and is viscid to about the same degree as glycerine. On evaporation we found that lysoform yields 43·04 per cent. of residue which contains the soap and some formaldehyde. Lysoform gives an excellent lather when rubbed on the hands after the manner of soap, so that when employed for antiseptic use two important agents are at work in bacteriologically cleansing the hands and rendering them aseptic. In the same way lysoform solution is admirably adapted for sterilising surgical instruments, having no corrosive effect upon metals. The solution shows an alkaline reaction. Lysoform has a feeble odour of formaldehyde but when diluted this odour is scarcely perceptible. It may be used on account of its non-irritating properties for cleansing the nasal or oral cavities and for the purpose of a vaginal or uterine douche. Internally in small quantities lysoform appears to have no poisonous action, so that relatively speaking it is non-poisonous. It forms the basis of many excellent toilet preparations, as for example lysoform soap, lysoform tooth paste, and lysoform mouth wash. We found the soap to be free from alkaline excess and, in fact, it contains on the contrary an excess of fat. Petroleum ether, according to our experiments, extracted 2·30 per cent. of unsaponified fat. The properties of lysoform are such as to render it a safe, convenient, and effective antiseptic.

"TABLOID" SPARTEINE SULPHATE.

(Burroughs, Wellcome and Co, Snow Hill-buildings, London, E.C)

On account of its diuretic properties and of its value as a cardiac tonic sparteine has been recommended to be tried when digitalin fails. It is said, in fact, to succeed occasionally when that drug does not. The tabloid of sparteine sulphate contains one grain of the salt and is intended for administration by the mouth.

"LASSO" SOAP.

(Edward Cook and Co., Bow, London, E.)

"Lasso" is a soap manufactured especially for the purpose of removing grease and stains from the skin and we find that it fulfils this purpose admirably. According to our analysis it contains a well-known mechanical detergent which materially assists the soap itself. The soap basis is of excellent quality and free from alkaline excess. The soap is very effectual in removing all kinds of tenacious grime.

COCOA AND MILK.

(J. S. Fry and Sons, Union-street, Bristol)

This is a convenient dietetic preparation made with cocoa and milk, consisting of a paste which, when stirred in hot water, gives at once a refreshing cup of cocoa ready for use. According to our analysis the preparation contained 8·96 per cent of moisture, 1·40 per cent. of mineral matter, and 12·08 per cent. of fat. The preparation affords a means of readily obtaining a refreshing and nutritive beverage. It is, however, somewhat sweet.

CARLSBERG BEER.

(Agency, Max Hartvig, 46, Queen Victoria-street, London, E.C)

We have examined both light and dark specimens of Carlsberg beer and it is claimed that they show a relatively low alcoholic strength. The beers are pasteurised. They were found to be in excellent condition, sound, bright, and sparkling. The flavour of each was characteristic of a pure malt and hop infusion. The dark beer gave on analysis the following results: malt extractives, 4·04 per cent.; mineral matter, 0·17 per cent.; maltose, 1·90 per cent.; and alcohol, by weight 1·69 per cent., by volume 2·12 per cent, equal to proof spirit 3·71 per cent. As will be seen, the amount of alcohol is quite small and the beer may be regarded certainly as non-intoxicating. *We could trace no objectionable preservatives.* The light beer, of the type of Pilsener beer, gave the following results: malt extractives, 3·53 per cent.; mineral matter, 0·09 per cent.; maltose, 1·75 per cent.; and alcohol, by weight 2·56 per cent., by volume 3·21 per cent., equal to proof spirit 5·61 per cent. This beer was in excellent condition but its alcoholic strength is decidedly higher than that of the dark specimen. Such excellent light alcoholic beverages are calculated to help the cause of true temperance.

SPECIALLY SELECTED HIGHLAND WHISKY.

(JOHN BISSET AND CO., 37, QUEEN-STREET, ABERDEEN.)

On analysis this whisky gave the following results: alcohol, by weight 42·76 per cent., by volume 50·31 per cent., equal to proof spirit 88·18 per cent.; extractives, 0·14 per cent.; and mineral matter, 0·07 per cent. In regard to secondary products the following were the results given in grammes per hectolitre of absolute alcohol present: acidity reckoned as acetic acid, 24·00; aldehydes, 25·00; furfural, 2·88; ethers reckoned as acetic ether, 42·24; and higher alcohols, 160·00 These results are quite in accordance with the statement that Highland malt spirit is for the most part used in the blending. The figures indicate some addition of grain whisky. There can be no doubt, however, that the whisky is well matured; it is soft to the palate and possesses an acceptable malty flavour. It is quite free from any suggestion of raw products and is therefore dietetically suitable.

"DARTRING" LANOLINE TOILET SOAP.

(BURROUGHS, WELLCOME AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

The advantage of lanoline soap for toilet purposes is obvious, since it contains, according to our analysis, an excess of fat amounting to slightly over 5 per cent. and this fat, it is important to add, is chemically identical with the natural fat of the skin. Whilst, therefore, lanoline soap is an efficient detergent it does not render the skin dry and hard but soft and supple.

OLD HIGHLAND MALT WHISKY.

(THE BARLEYCORN CO., LIMITED, 3, RANGOON-STREET, CRUTCHED FRIARS, LONDON, E.C.)

We have carefully examined this whisky and believe from the results of analysis that it is correctly described as a pure malt spirit. The figures were as follows: extractives, 0·09 per cent.; mineral matter, 0·01 per cent.; and alcohol, by weight 41·80 per cent., by volume 49·39 per cent., equal to proof spirit 86·37 per cent. The following figures relate to the secondary products in the whisky recorded in grammes per litre of absolute alcohol: acidity reckoned as acetic acid, 12·0; aldehydes, 20·0; furfural, 3·08; ethers reckoned as ethyl acetate, 72·16; and higher alcohols, 240·0. The results are typical of the genuine all-malt pot still spirit. The whisky is well matured and of good but somewhat "full" flavour.

SERILA BOUILLON EXTRACT.

(AGENTS: E. S. SHULTES AND CO., 158, PALMERSTON HOUSE, OLD BROAD STREET, LONDON, E.C.)

This preparation may be correctly described as a bouillon extract but the proportion of beef nutritives in it is quite insignificant. To start with it contains, according to our analysis, 41·10 grammes per cent. of solid matters, of which no less than 37·48 grammes consist of mineral matter, containing 26·03 grammes of common salt. According to these figures there remain but 3·62 grammes of total organic matter. It is true that this contains proteids but we cannot endorse the claims made in regard to this preparation that it possesses any special or high nutrient value.

TROMMER'S EXTRACT OF MALT PREPARATIONS.

(THE TROMMER EXTRACT CO., 44, CHARTERHOUSE-STREET, LONDON, E.C.)

The basis of the preparations about to be described is an extract of malt of a very satisfactory character. We have proved *in vitro* its digestive action upon starch. The extract is of good flavour and contains a commendable proportion of the nitrogenous principles of malt. Amongst the compounds made with this active malt preparation is the Trommer extract of malt with 33 per cent. of petroleum. It is stated that the Trommer extract of malt emulsifies oils by virtue of a ferment closely allied to emulsin or lipase. Whether or not that be so there is some difference of opinion as to the value of petroleum oil at all within the human economy. It is stated by some authorities that the whole of the petroleum administered may be recovered from the fæces unchanged. Considering the chemical stability of petroleum such a result might be anticipated. The Trommer extract of malt is also combined with cod liver oil and the hypophosphites—an excellent emulsion,—with cascara sagrada, with pepsin, and with yerba santa.

MEDICINE AND THE LAW.

Suicide by Prisoners.

IN consequence of the suicide which recently took place in a cell at the Old Bailey, when a prisoner named Barmash shot himself, the attention of the Home Office has been directed to the possibility that persons upon bail may come to trial provided with means of committing suicide should the verdict prove adverse or that these means may be conveyed to condemned prisoners during the farewell interview with relatives which is usually permitted. A circular letter in which the Home Secretary conveys his views to local benches of magistrates upon this subject uses the expression "dangerous weapon" in this connexion, but no doubt the employment of poison would have to be guarded against even more carefully than that of firearms should any considerable tendency to suicide in such circumstances be observable. The Home Secretary does not, however, think the danger sufficiently serious to necessitate the searching of all bailed persons, although he recommends it as necessary in some cases. With regard to the interviews with relatives he advises that these should not take place in the court cells except where there is proper accommodation. Presumably the law relating to the sale of poisons is efficacious enough with regard to the classes from which criminals are chiefly drawn to prevent them from obtaining the means of death from the druggist without some little difficulty. It is, however, to be observed that the villain who contrives at the last moment hastily to swallow something from a phial and so to "cheat the gallows" exists principally in the works of the sensational novelist. Many cases of murder and suicide occur in which the two acts follow closely upon one another and are the result of a common impulse and there are also instances from time to time of self-destruction following the detection of crimes which in themselves suggest conditions of mental unsoundness. The majority, however, of those who deliberately violate the law either in order to enrich themselves or for some other purpose are not driven to take their own lives by the mere fear of imprisonment or even of death at the hands of the executioner.

Carbolic Acid as a Poison.

IN THE LANCET of Oct. 17th, p. 1113, attention was called to the frequent occurrence of carbolic acid as a means of suicide or as a cause of accidental death. A very similar case to the one then commented upon was inquired into at the coroner's court at Battersea on Oct. 31st. The evidence showed that the deceased, the wife of a clerk, had two bottles in her bedroom, one containing whisky and the other carbolic acid, and that in the dark she poured carbolic acid into a cup and swallowed it believing it to be whisky. There was no evidence pointing to suicide and when first found she said that she thought she had "taken something in mistake." The woman's husband stated that she was sober at the time but "had been rather a heavy drinker and had lost her sense of taste somewhat." It is easy to understand that many consumers of whisky are indifferent as to the nature of the grain from which their beverage is distilled and as to questions of maturity when one who is only "rather" a heavy drinker cannot either by taste or smell distinguish carbolic acid from it in the dark. To devise precautions that will protect such persons seems to be almost impossible. A stopper of peculiar construction rendering it more difficult to remove than the ordinary cork or stopper might be devised and insisted upon at the sale of poisonous drugs. Such a contrivance would enforce the attention of the person opening the bottle more effectually than the fact of its differing from other bottles to the touch. The use of a particular bottle or stopper, however, cannot be enforced after the completion of the purchase.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 7, 1903

The Presidential Address at the Ophthalmological Society of the United Kingdom.

THE Ophthalmological Society is to be congratulated on having for its President during the ensuing year the distinguished surgeon who holds the still more prominent office of President of the Royal College of Surgeons of England. It must be acknowledged that the combined duties of the two positions will weigh heavily even upon the energies and the ability of so accomplished and strenuous a man as Mr. TWEEDY, but if we are compelled to regret that his Presidential Address to the society upon the Relations of Ophthalmology to General Medicine and Surgery and to Public Health (which will be found at p. 1280 of our present issue) has been confined within somewhat narrow limits, touching but slightly upon certain topics of great importance alike to ophthalmologists and to the public, we do so with the full knowledge that with Mr. TWEEDY actions come before words. Time may fail him to prepare addresses but we feel certain that he will always find leisure to discharge with zeal and exactitude his official duties. Mr. TWEEDY was at first inclined, he told his audience, to regard the delivery of an address as a matter of form from compliance with which he might seek to be excused, and when this suggestion was repudiated by a flinty-hearted surgical secretary he next thought of "saying ditto to Mr. BURKE" by giving utterance to a series of passages compiled from the addresses of his predecessors in the chair. Kinder counsel, however, prevailed, with the result that the President of the day made a personal addition to the edifice of thought and knowledge which has been prepared by those who had previously occupied his seat. The members of the society, while fully prepared to endorse their President's praise of the addresses given by the long list of brilliant men whose names he enumerated, would not on that account have been less anxious to receive guidance from Mr. TWEEDY himself; they were gratified to listen to his matured opinions upon the questions of the hour and only regretted the brevity of his address.

It was manifestly almost a necessity on such an occasion to say something not only on the general relations which should exist between special branches of practice and medical science as a whole but also on the particular position of ophthalmology in this respect. The new President struck a true note by reminding his hearers that the society had been formed by men who were interested in the study and investigation of diseases of the eye, not merely as local affections but also in their relations to general disease and more particularly to disease of the cerebro spinal system, and he urged upon the younger members the importance of withstanding any temptations to narrow the scope of their corporate endeavours. While admitting the necessity of specialism he pointed out that all specialists should keep in intellectual touch with the developments of modern medicine and with the general progress of pathological knowledge, or, as the idea might perhaps be expressed in other words, that they should think of their art as a department of general medicine and surgery, and of the organs with which it deals as integral portions of a living mechanism in the derangements of which they are liable to share. He regretted an apparent tendency even within the profession, and still more outside its ranks, to split up practical ophthalmology into two parts, the optical and the medico-surgical, and declared that this tendency ought to be jealously resisted not only in the interests of our art but in those of public health. The eye is not, he urged, only an optical instrument but is a living mechanism made up of the most elaborate and most highly differentiated structures in intimate and constant relation with the cerebro-spinal system, the blood-vessels, the lymphatics, and the other organic systems of the body, living the life of the whole body, observing its modes of nutrition, participating in its diseases, and responding to its various pathological manifestations. No one, then, can safely deal with the optical defects of the eye unless he has an adequate knowledge not merely of its structural diseases but also of their relations to the whole of the organism.

The passages of the address which we have thus quoted or abbreviated will commend themselves to our readers as being demonstrably true and are in complete accord with much which we have previously written on the same subject. They *leave nothing to be desired in respect* either of accuracy of statement or of comprehensiveness of view, and they amount to an absolute condemnation of the "ophthalmic optician," or "optologist," or whatever he may please to call himself, and of all his ways and works. They contain an explicit repudiation of the belief that what are called the optical defects of the eye can ever be safely or satisfactorily treated apart from a knowledge of the diseases to which that organ is liable or of the manner in which it may participate in the diseases of the body as a whole. Such a declaration as this, proceeding from one who is not only the president of a special society but also the President of the Royal College of Surgeons of England, could hardly have been made in too emphatic terms. We doubt if Mr. TWEEDY'S words would have gained in force by amplification, while their direction is so clear that although uttered to a scientific audience their message could not have been better calculated to convey instruction to the public. Members of the medical profession, whether specialists or not, do not need to be told that the proceedings of a spectacle quack are fraught with danger to his misguided customers, or that the various forms of apparatus, more or less complicated, which are displayed at places of public resort may prove traps for the unwary. But a warning is needed to reach the public ear and to make an impression on what is called the public mind. The fact is that the advances of ophthalmology and the knowledge recently gained concerning conditions which spectacles may relieve have brought about the development of a new and dangerous form of charlatanism which is seeking, by all the usual means of impudent advertisement and unblushing false pretence, to bring grist to the mills of its professors at no matter what danger to the sight of the credulous or the ignorant. In the presence of such conditions it is hardly possible for the medical profession to speak too plainly, and we hope that Mr. TWEEDY'S words may filter through that profession and the press to the public so that the obvious lessons may be learned from them. The strong position occupied by the speaker as head and official mouthpiece alike of a powerful medical corporation and a famous scientific society should secure fruitful consideration for his words. They cannot be brushed aside as expressing any narrow or specialistic view.

◆

The Personal Paragraph.

SEVERAL references have recently been made in the columns of a contemporary journal to the ethics of what may be conveniently termed the personal paragraph, so far as it relates to medical men and their patients. The correspondence commenced with the communication of a resolution, emanating from the ethical committee of the British Medical Association, which runs as follows: "That a circular letter be sent to the principal London newspapers deprecating the mention in paragraphs relating to the illnesses of persons, other than members of the Royal Family, of the names of medical men in attendance." The letter sent with this resolution states that it is believed that in general the information is supplied by the patient or his friends and that the medical man is not consulted as to the insertion of his name and if consulted would object. Other letters have since appeared protesting strongly against any organised interference with the liberty of the press and urging that a man of talent is entitled to have his meed of praise in the lay press when it is deserved and clearly claiming that there is financial advantage in such paragraphs and that many are debarred from sharing in this legitimate gain by the influence of a clique. "Sweet are the uses of" advertisement and the writers of these letters object "to let concealment, like a worm i' the bud," injure their prospects in life. They argue so strongly that they cast doubt upon the original charitable suggestion that the personal paragraph is "supplied by the patient or his friends."

Assuming the absence of connivance and unworthy prompting there may be reasons for these paragraphs being sent by the patient or his friends in all good faith. They might be suggested by the desire to claim sympathy in a time of sickness and to reassure friends, not only by stating the nature of the complaint, but also by indicating the name of the medical man in attendance or that of the physician or surgeon in consultation. It is conceivable that such a paragraph might be sent to the papers to avoid the trouble and annoyance of unnecessary suggestions from relatives and acquaintances. There is a strange tendency amongst the public to offer advice upon all matters, most of all, perhaps, upon questions of health; it is doubtless well-intentioned though often ignorant and disquieting. It is the tendency which leads to random recommendations of quack remedies, of fashionable health-resorts, and even of the names of members of the medical profession. At its best the personal paragraph may serve to check all sympathetic but ignorant suggestions, since by plainly stating the nature of the illness and the name of the practitioner it indicates, or may be intended to indicate, that though there may be cause for anxiety the patient and his relatives are aware of the risks and are doing their best to avert danger. In this sense, and perhaps in this only, is the personal paragraph legitimate and defensible. There is, however, another argument which might be urged on behalf of publication by the patient and his friends. Having presumably paid a high price for an operation by a distinguished surgeon, are they not at liberty to proclaim the fact and to derive some supposed social advantage from the association of their name with that of one known to have attended exalted personages? In other words, may not the advertisement occasionally be intended for the benefit of the patient rather than of the medical practitioner whose name has been introduced without his permission and regardless of his feelings?

To judge from some of the letters which have appeared upon this subject there is a strong feeling that the personal paragraph does not originate in either of these ways, that it may be sent by the medical man, and that it is not more frequently seen because of "an imposed incubus of chaste restraint" which "will not allow a man of talent to have his meed of praise in the lay press when it is deserved." "Chaste restraint" should hinder publication of the names of patients and the nature of their maladies, since there can be no public advantage in supplying material for unprofessional inquiries into the etiology of disease, whether it is to be attributed to personal habits or to inherited weakness. Guided by the dictates of good taste the consensus of professional opinion is against the disclosures of the lay press, since they tend to undermine confidence in the reticence of the medical attendant and when this is lost surely practice goes with it. Those who have written in defence of the personal paragraph appear to regard it as a royal road to fortune and think its suppression an act of injustice, but in its ordinary form it affords no measure of "praise when it is deserved," since it merely announces the name of one who has been consulted or who has been called upon to operate, and it does not record whether the advice has been acted upon or whether the operation was one involving greater difficulties or more deserving of praise than thousands of minor operations daily performed by juniors in ordinary hospital routine While all sympathy must be extended to those—and they are numerous—who feel they have not yet reached the professional position to which they consider that they are entitled by their abilities, by their long period of preparatory study, and by their conscientious discharge of all professional duties, we would still in their own interests deprecate any endeavours by personal paragraphs to take a short cut towards success, since we believe that this frequently entails loss of confidence by patients who do not desire publicity and loss of respect amongst professional brethren who scorn those who do.

Physical Disability of Recruits for the Army.

ON the physical well-being of a people their national existence itself may depend. The mental activity of the inhabitants of a country is obviously of the utmost importance if they are to maintain an intellectual, scientific, or manufacturing supremacy over their rivals and nowadays the claims of higher education, especially in technical subjects, have been very extensively advanced, and though we do not wish for one moment to belittle their importance we consider that at present there is small chance of the needs of mental education being disregarded. There is, however, a risk that the physical education of certain sections of the community may not have due recognition. It was only natural that the long-continued neglect of technical education in this country should be followed by a reaction and the reaction has led to a certain amount of disregard of the importance of physical health and thus physical education is at the present time distinctly under-valued. The hackneyed phrase "*mens sana in corpore sano*" exactly expresses the desired consummation. "These ought ye to have done and not to leave the other undone." To neglect either the mental or the physical training of the child or of the nation is a serious error; the two should proceed *pari passu.* Especially in the *personnel* of the army and navy is physical strength of importance, for vain indeed would be an appeal to physical force if the physical force itself should prove wanting.

A doubt has arisen, and to this subject we have frequently referred, as to the quality of the raw material which offers itself to the recruiting sergeant, for it has been suggested that there is an obvious falling off in this respect and it has been thought that the deterioration has been proved by statistics. It is, at all events, certain that during recent years a large number of recruits for the army have been rejected on the ground of physical disability and it was proposed that the Government should institute an inquiry as to the causes which have led to this apparent falling off in the national health. To this end, as we mentioned in THE LANCET of July 25th, p. 246, the Director-General of the Army Medical Service prepared a circular containing statistics bearing on the subject and this circular was sent by the Secretary of State for Home Affairs a short time ago to the Council of the Royal College of Surgeons of England with a request for any observations on it which the Council might feel disposed to make. The Council has now made public its reply, which was hitherto confidential, and it deals with the question of the necessity for an inquiry into the causes of physical deterioration and into the means available for improving the national health. The Council bears testimony to the skill and clearness with which the Director-General has drawn up his report on a very difficult and intricate subject. The circular states *in limine* that there is reason to believe that the physique of the well-to-do classes of the country is improving and we do not think that there will be any difference of opinion on this point for it is a matter of common knowledge. The increased attention devoted to the physical exercise of girls also cannot but have its effect on the next generation. The circular goes on to say that "a very large proportion of the men who offer themselves for enlistment in the army are found to be physically unfit for military service," and it appears to be suggested that the proportion of those who are unfit is increasing. The Council does not consider that the statistics which are contained in the circular really bear out these views. It is necessary in the first place to be sure that there has been no change in the requirements as to the physical fitness of recruits for the army during the few years to which the statistics refer, for any such change would obviously deprive the statistics of their value, but no alteration appears to have been made, nor has there been any increased stringency in the application of the tests imposed. The men who now wish to enter the ranks of the army are drawn from a class physically inferior to that from which they came in former years and it is to this cause that the Council mainly ascribes any deterioration that there may be in the quality of the recruit Putting aside the comparatively few who take up soldiering from a real liking for a military life, most of the recruits are men who have been unable to obtain other work. The Council points out that during recent years many influences have combined to affect the status of the working classes. Increased competition in trade, the "labour movement," trade unions, and many other social and economic factors have modified the conditions of labour and have raised the standard of efficiency of the workman, the standard of living, and the rate of wages. This competition leads to the better educated and the more physically fit obtaining higher wages now than formerly; hence it follows that there is a greater difference now between the pay offered to the private soldier and the wages which can be earned by the working man. It is only from the residue, who from some mental or physical unfitness fail to obtain regular employment, that the men who offer themselves for enlistment are drawn

In spite of the probability of there being some falling off in the quality of the recruit the Council was unable to find that the physical disabilities have increased. One table in the circular gives the proportion of rejections of boys under 17 years of age; only 11·2 per cent. were rejected and it cannot be said that this is a large proportion when we bear in mind the numerous possible physical disqualifications. Rejections are distinguished as primary and secondary. Primary rejections are those which occur at the first examination for enlistment and secondary rejections are those occurring within three months of enlistment or after two years' service. There has been a steady fall in the rate of primary rejections from 40·6 per cent. in 1893 and 41·6 per cent. in 1896 to 27·4, 28 0, and 30·7 per cent. respectively in the three years 1900 to 1902, but in 1901 and 1902 there was a sharp rise in the percentage of secondary rejections, though it is difficult to say what is the explanation of this rise. The table giving the causes to which the rejections are assigned shows a diminishing proportion for every cause except "loss or decay of teeth." The numbers rejected for "chest measurement" and for "imperfect constitution and debility" have greatly diminished, while the rejections due to the teeth have increased nearly five-fold in the 12 years 1891 to 1902. Assuming that no change has been made in the requirements the Council believes that many of the causes of disability will grow less and that "the spreading influence of the various social, municipal, and philanthropic agencies for the promotion of the public health and the strengthening of the character of the individual cannot fail to affect beneficially the health and wellbeing of all classes of the people," and with this hope we concur. It must not be forgotten that many of the disqualifications which exclude a would-be recruit from the British army are considered of much less importance in countries where conscription obtains. In conclusion, the Council states that it does not consider that there is any need for a large inquiry into the national health but it is of opinion that "much might be done by emphasising the necessity of still stricter attention to the health, feeding, and training of school children, and more especially the care of the teeth and the arrest of threatened or early decay." The Council also considers that "as much as possible should be done to promote the health, growth, and general physical development of the young soldier by improving his environment and by the exercise of special care in the selection of the kind and quality of his food and in its preparation and preservation."

As we have already announced, the Government has appointed a very satisfactory committee to investigate the whole subject. We shall probably have to wait several months for its report, as such investigations are carried on somewhat slowly, but when it is issued it should prove of the greatest interest to the whole nation.

Annotations.

"Ne quid nimis."

KING EDWARD VII. SANATORIUM.

ON Nov. 3rd the foundation-stone of this sanatorium was laid by His Majesty the King at Lord's Common, Midhurst, before a large gathering of visitors, the majority of whom consisted of members of the medical profession and their wives or daughters. The King in his speech referred to the benefits likely to be conferred on the community by a sanatorium of the character which it was proposed to build. It is intended not for the accommodation of the very poor—they are already provided for—but for the relief of those of slender means who are unable to meet the expenses of prolonged residence in private sanatoriums. The original plan of reserving a certain number of beds for more wealthy patients will also be persisted in. His Majesty also laid stress on the fact that while no necessary comforts which will add to the well-being of the patients will be omitted there will be a total absence of all luxury and of expenditure of money in superfluous appointments. This arrangement is entirely what might be expected, emanating as it does from a committee formed of gentlemen who have had both large and special experience in the management of hospitals and kindred institutions. Sir William Broadbent, as chairman of the advisory committee, in a brief address referred to the care which had been taken in selecting a suitable site and the difficulties which had been met with in obtaining a good water-supply. Both these essentials are now all that can be desired. The general arrangements for the day were most efficiently carried out. The invited guests were conveyed to Midhurst and Haslemere stations respectively by special trains and vehicles were in readiness to take them to the site of the sanatorium. After the brief ceremony of laying the foundation-stone the King at once returned to London, whilst luncheon was served to the large party that had been invited, and subsequently ample time was allowed to view the preparations which have already been made for the construction of the building. The architect's plans were also on view. In addition to the interest of the occasion a most enjoyable day was spent by those who had the privilege of being present, the drive to Lord's Common giving an opportunity of viewing the beautiful scenery, rendered even more lovely than usual by the glorious autumnal tints.

THE ST. BARTHOLOMEW'S HOSPITAL APPEAL.

IN THE LANCET of Oct. 31st, p. 1247, we alluded shortly to Sir Henry Burdett's paper in the *Hospital* of the same date concerning the future of St. Bartholomew's Hospital and in one place we unwittingly committed a slight inaccuracy. We stated that Sir Henry Burdett did not say whither he would propose to remove the nursing home, but we see on closer inspection of his article that he mentions that the existing wards, when the patients would be removed into the new wards which he proposes to construct, would suffice for the nurses. The question of the future of St. Bartholomew's Hospital is so important that we think it is as well to state succinctly how matters exactly stand. For some years past it has been obvious to the authorities of the hospital that more land must be acquired for the purpose of reconstruction and augmentation of the existing buildings and on Feb. 25th, 1902, Lord Balfour of Burleigh, who was the appointed arbitrator in the dispute between the authorities of St. Bartholomew's Hospital and Christ's Hospital, gave it as his decision that St. Bartholomew's Hospital should be given an area of a little more than one and one-third of an acre at a cost of £238,781.[1] The area thus granted is very nearly the same as that marked in a map which we published in our issue of August 11th, 1900, p. 408. What is now required is, as we said last week, some two more acres of land. This would cost about another £250,000. To erect the necessary buildings upon this area and the area at present in the possession of the hospital, including the removal of some of the existing buildings, would cost, in all probability, another £500 000. The Mansion House Committee has already decided to appeal for £350,000, but it seems to us that in view of the great importance of the matter it would be as well for the governors of the hospital to take a bold step forward and to appeal to the public not merely for £600,000, as suggested by Sir Henry Burdett, but for £800 000 This it may be calculated would cover with a certain margin to spare the cost of the additional two acres which we suggest are necessary for the due extension of the hospital and the erection of new buildings together with the renovation of the old. We think that, if the public were certain that the authorities of St Bartholomew's Hospital were willing to undertake a great scheme which would be practically final, the £800,000 might not be long in forthcoming. It is an enormous sum, and when the wants of other hospitals and the urgency of other appeals are remembered we may seem over sanguine as to the result of a public appeal for such a mass of money. But St. Bartholomew's Hospital has behind it a history of upwards of eight centuries. It is the only hospital within the boundaries of the City of London. It has stood where it now stands since the day when the first stone of it was laid. Medical men and others who have been connected with it are scattered throughout the empire and we believe that an appeal to the generosity of the citizens of London, to the subjects of the King whose son is now, like his father before him, the President of the hospital, would meet with a response worthy of the name and fame of that great institution founded so many years ago by Rahere.

---

[1] THE LANCET, March 1st, 1902, p. 611.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members will be held at the College on Thursday, Nov. 19th, at 3 P.M. Any motion to be brought forward at the meeting must be signed by the mover or by the mover and other Fellows and Members, and must be received by the secretary at the College not later than Nov. 9th. At this meeting the annual report of the work of the Council will be presented. A copy of this report will be sent to any Fellow or Member on application, and on request the name of the Fellow or Member can be registered, so that the report can be sent to him annually without further application. It is important that as many Fellows and Members as possible should attend this meeting, so that any motions which may be carried may really represent the opinions of the body corporate.

THE "RED LIGHT" TREATMENT OF SMALL-POX.

DR. J. F. SCHAMBERG, professor of diseases of the skin in the Philadelphia Polyclinic and College for Graduates in Medicine, has submitted to us a criticism of Professor Finsen's views on the red light treatment of small-pox which are well known to the readers of THE LANCET. Dr. Schamberg's remarks refer perhaps more particularly to an article which appeared in the *British Medical Journal* of June 6th, 1903, by Professor Finsen but they are of considerable interest as showing the very varied opinions which have been expressed on this method of treatment. The failure to take into consideration the type of cases in any particular epidemic of infectious disease has frequently led to misconception in regard to the value of a new remedy. Doubtless the fact that epidemics of small-pox vary greatly in the case mortality may account in some measure for the different results obtained by the Scandinavian physicians on the one hand and the American physicians on the other, and Dr. Schamberg refers to this point in his remarks. Professor Finsen was enthusiastic with regard to his results and remarked that "the effect of the red light treatment is one of the most striking results known in medicine" and that "we cannot help comparing the red light treatment with vaccination." Dr. Schamberg attempts to refute these statements both on theoretical and practical grounds. Professor Finsen maintains that the chemical rays of sunlight exert an injurious influence on a diseased skin and that the use of red panes of glass or red curtains in a room excludes the chemical rays and he adduces this theory as an explanation of the alleged benefit of red light in cases of small-pox. Dr Schamberg contests this view and his arguments seem to be well founded. He points out that while prolonged exposure to the direct solar rays, particularly in the hot months of the year, commonly induces inflammatory reaction, yet there is no evidence of such noxious influence from ordinary exposure to diffuse daylight. Further, small-pox being more prevalent in the winter months, it seems difficult to believe that ordinary exposure in the sick room to diffuse daylight at that time of the year would result in any irritative action of the skin. Dr. Schamberg also is of opinion that the predilection of the small pox eruption for the face and the extremities is not because these parts are exposed to light but that it is due to their greater vascularity. Dr. Schamberg refers to the favourable opinion of the treatment expressed by physicians chiefly in Denmark, Sweden, and Norway. His own experience is limited to two cases of the disease, both of which ran an unfavourable course. He refers, however, to an article by Dr. N. D. Brayton of Indianapolis. This physician treated 300 cases in "red light wards" and was entirely unable to corroborate the good results claimed by the Scandinavian medical men. As partially explanatory of this discrepancy Dr. Schamberg points out that Denmark, Sweden, and Norway are among the best vaccinated countries of Europe. It is obviously illogical and misleading to attribute definitely favourable results to certain measures employed in the treatment of small-pox in persons once vaccinated. It is evident, therefore, that no absolute conclusions can yet be drawn with regard to the red light treatment. Further evidence is necessary. He insists that the general severity of the particular epidemic must be noted and also whether the patients so treated had ever been vaccinated, or whether revaccination had been performed at a comparatively recent period.

STREET NOISES.

WE have upon several occasions drawn attention to the very great and absolutely unnecessary nuisance caused by newsvendors shouting their wares in the streets. We have also pointed out that the view which some magistrates take that a complainant must appear in person renders the existing law on the subject absolutely useless. We are glad to see, however, that one magistrate at least has apparently considered that the recently passed by-law of the London County Council is enough for him and the police to act upon without the attendance of an annoyed ratepayer. On Oct. 28th seven newspaper boys appeared before him for shouting in the streets. Six of them were fined 2*s.* 6*d.* and 2*s.* costs each, and one, who was very small, had to pay 1*s.* and 2*s.* costs. The nuisance in a street such as the Strand which is full of workers is absolutely unbearable and, as we have pointed out again and again, there are lots of newspaper sellers who do not shout and who do not rush through the streets like lunatics. The police are exceedingly loth to act upon their own initiative but it is perfectly foolish for legal authorities to expect anybody who is at work to leave his occupation, to run downstairs, to find a policeman, to follow up the newspaper seller, to take his name and address, and to promise to appear at some future date at a police-court. What is wanted is that any newspaper seller who persistently shouts should be then and there taken to a police-station.

WORKHOUSE NURSING.

THE matter of nursing in workhouses has already been dealt with at some length in these columns but its importance justifies some allusion to the proceedings at a meeting held on Oct. 29th in connexion with the Hospitals Association. This meeting, which took place at St. Thomas's Hospital, Mr. Thomas Bryant being in the chair, was held for the purpose of considering the Report on Nursing of the Departmental Committee which was appointed by the President of the Local Government Board. In opening the discussion Dr. T. D. Savill found fault with the constitution of the committee in that while the Local Government Board was fully represented no outside expert on nursing was invited to assist. He opposed the arrangement by which it is proposed to grant certificates to nurses after 12 months' training on the grounds (1) that the material afforded by cases in workhouses is not sufficient for adequate training, especially as the medical and surgical methods pursued there are not always up to date; and (2) that the time is too short both for gaining experience and for the formation of that character of broad-minded intelligent sympathy which constitutes so important a part of a nurse's qualification. It was pointed out that the object of the Local Government Board was to manufacture cheap nurses for employment in workhouses, and stress was laid on the injustice which would be done to nurses of the better class by giving credentials of apparently equal value to imperfectly trained women. Miss Gibson, matron of the Birmingham Infirmary, regarded the suggestion that a new grade of nurses, to be called "qualified nurses" and with only one year's experience, should be instituted as dangerous and retrograde in the extreme. She agreed with Dr. Savill as to the impossibility of any woman obtaining in a year at a small workhouse such knowledge as would render her a safe person to be left in charge of patients without supervision. Skilled nursing, she remarked, is a necessity for all who are sick and she expressed the opinion that it was a gross injustice to the sick poor that so low a standard of knowledge as the report sanctions should be accepted. Dealing with the question of the position of superintendent nurses she supported the proposal of the committee to make those officers independent of the matrons and pointed out that any course which tended to reduce the responsibility and the enthusiasm of the Poor-law nurse tended to lessen the supply and to lower the quality of such nurses. Reform, in Miss Gibson's view, should take the direction of (1) the formation of a special nursing department of the Local Government Board; and (2) the appointment of women inspectors who were nursing experts to visit, to inspect, and to report on the nursing of the small unions. In this way she thought that the debt of gratitude which she described the sick poor as willing to pay would be largely added to. Several other speakers, including Mr. J. T. Macnamara, Mrs. Despard, and Mrs. Bedford Fenwick, followed in the same sense and a motion proposed by Dr. Savill was passed unanimously condemning the proposals of the Local Government Board and urging that their adoption would have a detrimental effect upon nursing generally. It was also decided to ask the Local Government Board to receive a deputation in connexion with the subject. With the aims of the promoters of the meeting, in so far as these are directed towards maintaining the efficiency of nursing in all its branches, we are quite in sympathy. It is eminently desirable that there should be no ambiguity about the qualifications of nurses and this will certainly arise if the Local Government Board persists in applying the epithet "qualified" to a nurse as an indication of her having received a minimum of training.

SECOND ANNUAL REPORT OF THE WORK OF THE BACTERIOLOGICAL LABORATORY OF THE WEST RIDING OF YORKSHIRE COUNTY COUNCIL.

THE number of county medical officers and of county public health laboratories will no doubt steadily increase as the public realise the value of the services which are rendered by them in the preservation of the country from the spread of epidemic disease. Such annual reports as the one under notice will greatly assist this realisation. The West Riding County Council having established a laboratory offered to undertake free of charge such bacteriological investigations as would be of assistance in the diagnosis of certain infectious diseases and of importance to public health. The need of a county laboratory has in other cases been met by the utilisation of the fully equipped establishments which were attached either to the provincial universities or other educational bodies and thus the services of skilled investigators have been secured at a comparatively small expense. There can be no two opinions as to the legitimacy of the expenditure of public money for the public health but care should be taken that the resources of the public laboratory are not employed for purposes which are but remotely connected with the public service. The West Riding Laboratory commenced work in April, 1901, and a steadily increasing number of cases has been dealt with. In the last nine months of 1901 some 863 specimens were reported upon as contrasted with 1700 during an equal period in 1902. The principal work has consisted in the examination of specimens for the bacillus tuberculosis and the bacillus diphtheriæ and for the agglutination reaction in enteric fever. In the case of diphtheria the use of Neisser's stain and the direct examination of the swab have been so successful that in 50 per cent. of the positive cases it has been possible to send a report within a few hours of the receipt of the specimen. Early diagnosis in diphtheria is of the greatest importance to both patient and practitioner and the laboratory is to be congratulated on this unusually high ratio of successful and rapid diagnosis. One of the most important and striking features of the report is the very complete clinical information of the cases submitted for examination which the director, Dr. P. J. Cammidge, has been able to obtain. This bears witness to the good feeling which exists between the central laboratory and the local medical officers of health and the general practitioners, without which it is impossible to carry on any successful work. It is of vital importance that the results of the laboratory should be correlated with the clinical details if these institutions are to produce really scientific work and to further the progress of preventive medicine.

TABES DORSALIS IN THE NEGRO.

TWO grave and incurable diseases of modern life are believed by some neurologists to have been acquired by the negro with civilisation—viz., general paralysis of the insane and tabes dorsalis. Of tabes in the negro, writes Dr. d'Orsay Hecht, instructor in neurology in the University Medical School, Chicago, in an article published in the *American Journal of the Medical Sciences* for October, it has been possible to obtain very few references in medical literature. Von Leyden quotes an apparently well established belief among medical men to the effect that "tabes occurs very rarely in the large number of syphilitic negroes" in the United States and in Africa, while the disease is also stated by local physicians to be rare in Cuba. Dr. Potts, physician to the Dispensary for Nervous Disease in the University of Pennsylvania, had not seen a single case of tabes dorsalis in the negro in eight years, and Dr. Burr had not seen a single case at the Philadelphia Infirmary for Nervous Diseases during 14 years. Dr. Hecht, having had the opportunity of seeing and studying "four undoubted cases of tabes dorsalis in coloured individuals," three of whom were females and one was a male, states that the clinical picture of the disease as exhibited in these cases in no way differed from the symptom-complex accustomed to be seen among the whites except, perhaps, in the fact that they were all of the "amaurotic type" of the disease. Dr. A. Plehn, who had studied the diseases of the negro in Western Africa and who had drawn up an official report on the subject to the German Government in 1895, states that of nervous disease he had only seen four cases of epilepsy and an occasional case of hysteria, which exhausts the list of neuroses to which the natives are liable. Dr. Hecht thinks that emancipation from slavery has brought to the negro all the vices and excesses of western civilisation, that tuberculosis, syphilis, and cancer are now deeply rooted affections among them, and that a slight admixture with the blood of white people has weakened the race. The inter-crossing with new blood has brought with it a tendency to acquire new diseases. "By an illegitimate and universal miscegenation with the whites the typical American negro of to-day has incorporated in his frame the deteriorating phenomena of his hybridity." The following is one of the four cases recorded by Dr. Hecht. The patient was a negro woman, aged 39 years, of healthy parentage, in whom there was a slight trace of "white" blood. As a child she suffered at the age of 12 years from rheumatism which became chronic owing to hard work and exposure At the age of 16 years she gave birth to an illegitimate child Prior to the birth of her second child at the age of 18 years she contracted syphilis from the man who was her husband Her present illness began at the age of 34 years with severe recurrent protracted headaches of an agonising character and progressive dimness of vision in the left eye which glasses did not seem to relieve Eventually she became quite blind in the left eye and dim of vision in the right eye Severe gastric "crises," "girdle sensations" about the waist paræsthesiæ about the feet and ankles, "lightning" pains in the legs, and a commencing ataxia of gait manifested themselves The sexual desire rapidly disappeared and some defect of control of the bladder and rectum developed Physical examination showed absence of knee jerks, optic atrophy with iridoplegia, and exaggeration of the plantar reflexes The slight ataxia soon disappeared The interval between syphilitic infection and the first manifestation of tabes was in this case, and in three other cases, in harmony with what has been observed in white races Optic atrophy was present in every one of the four cases and it was singular to note, states Dr Hecht, that as the optic atrophy became distinct the further advance of the ataxia was checked—a condition to which Benedikt of Vienna called attention 16 years ago Subsequent observations by Bonar of New York and Pierre Marie have emphasised the fact that almost invariably the onset of optic atrophy marks the arrest of the ataxic symptoms, a fact for which an explanation is now found, says Dr Hecht, in an ingenious theory of "compensation of nerve centres and tracts" recently propounded by Edinger The question as to why the negroes, amongst whom syphilis is a very common disease, should suffer very rarely from tabes is hard to answer as yet "As well might we seek to explain the absence of tabes in Bosnia and Herzegovina where, as we know, the most intense constitutional syphilis is rampant among the natives" Dr Hecht concludes that a constitutional variation has been wrought in the American negro by acclimatisation, by social environment, and more than all else by miscegenation, and from a critical and exhaustive study of the facts of his own and other cases he concludes that the last factor is, above all, essential to the production of tabes in a syphilised negro

RAILWAY TRANSPORT FOR SICK AND WOUNDED MEN IN TIME OF WAR

In the June issue of *Le Caducée* Surgeon-Major Duval of the French army discusses the question of railway transport for the sick and wounded in war time While on a tour through British India in 1897–98 he was greatly impressed by the completeness of the arrangements to that end which he found established throughout the entire railway system of the North Western Provinces Forming part of every train there were several third class carriages which answered admirably for ordinary traffic and could also be easily rearranged for the reception of sick or wounded soldiers in the recumbent position The seats and backs being moveable could be compactly stored in an adjoining van, leaving a framework suitably fitted with hooks and other appliances for the suspension of stretchers in two tiers The operation of converting one of these carriages into an ambulance took a few minutes only In the sides of each carriage there were folding doors wide enough to admit laden stretchers with ease and safety In ordinary circumstances a portion only of each door would remain available for the ingress and egress of passengers, the remainder being kept securely fastened in order to prevent accidents On his return to France Surgeon Major Duval instituted inquiries and found that with the exception of one or two specially equipped "sanitary trains" capable of accommodating a comparatively insignificant number of patients the army medical authorities would in the event of war be compelled to depend for the transport by rail of sick and wounded soldiers upon the ordinary baggage wagon, a species of vehicle which is rendered absolutely unfit for the purpose by its lack of suitable springs So long ago as 1882 Dr. Redard, principal medical officer of the State railways in France, drew attention to this subject in a report which he addressed to the head of the administration but apparently no action was taken in the matter Last year he again returned to the charge According to an annotation in the *Archives de Medecine et de Pharmacie Militaires* for August one of the French railway companies has already constructed 56 third class carriages with removeable fittings and containing wide doorways for the admission of litters and we are also told that Dr Redard has been authorised to inspect the existing rolling stock throughout France with a view to the conversion of suitable carriages for ambulance purposes

"ANTI-VIVISECTIONIST" METHODS IN THE TEMPLE

Now that the Bar has resumed its labours after the long vacation the attention of the benchers of the Temple may be called to a large placard which decorates a ground floor window looking into Elm court, Temple It is apparently placed there by someone interested in what is popularly called "anti vivisection" and consists of a picture of a gentleman in his shirt sleeves contemplating a small dog which sits "begging" before him upon a table Beside the dog stands a microscope and a box with articles intended to suggest surgical instruments, and under the whole is inscribed "The Last Appeal," with a reference to the "anti-vivisection" source from which this entirely absurd advertisement is taken The suggestion of the picture, of course, is that the gentleman in his shirt sleeves is being appealed to for mercy by the small dog which he is about to sacrifice with ruthless cruelty in the supposed interests of science The display is in very bad taste and if the windows of chambers in the Inns of Court are to be used for purposes of this kind it would be better that the posters exhibited should deal with matters more within the scope of the lawyer's calling and not be of a nature offensive to members of another learned profession

TUBERCULOSIS OF THE URETHRA

Tuberculosis of the urethra is very rare The following case which is recorded by Dr A L Chute in the *Boston Medical and Surgical Journal* of Oct 1st, is of great interest A married man, aged 35 years, who had never suffered from venereal disease was seen in March, 1902. Two years previously he began to suffer from painful and frequent micturition and the left inguinal glands rapidly enlarged Hæmaturia and slight urethral discharge occurred at times For a period there were painful erections and coitus was impossible The stream of urine gradually became smaller and micturition became more frequent When he came under observation he was micturating four times at night and frequently in the day His general condition was good and there was no urethral discharge With difficulty he passed a few ounces of urine in a very small stream which was followed by dripping The urine was pale, of specific gravity 1009 and contained a trace of albumin and a few shreds which on staining showed urethral and pus cells, cocci and bacilli, but no gonococci. The urethra felt like a stiff tube At a distance of one and a half inches from the meatus was a hard bulbous enlargement and there was another at the peno-scrotal angle. On moving the urethra laterally at this point distinct crepitus was obtained. A probe was passed as far as the bulb and gave a grating sensation as it passed the enlargements. In the left groin was a mass of hard glands three or four inches long and about an inch wide. In the right groin the glands were only slightly enlarged. The prostate was enlarged and on the right side a small hard mass was felt. The diagnosis was not clear. Gradual dilatation of the urethra relieved the frequency and difficulty of micturition. At first bleeding was produced but it gradually diminished. With an alligator forceps bits of calcified material were removed. They were composed of carbonate and phosphate of lime, with traces of magnesium compounds and triple phosphate. A search for tubercle bacilli proved negative. In July, 1902, the left inguinal glands were removed. They showed amyloid infiltration, a condition which, apart from general amyloid disease, is very rare and usually is due to tuberculosis in some part of the lymphatic area. In April, 1903, a No. 25 (French measurement) sound could be passed. Grating could be felt at a point one and a half inches from the meatus and in the membranous urethra. On several occasions small pieces of calcified material were passed. Endoscopy showed a pale, fibrous-looking canal with an occasional eroded spot and whitish points here and there. Though the bacillus was not found the diagnosis of tuberculosis seemed justified by the non-venereal origin of the disease, its course, and the condition of the inguinal glands. Dr. Chute has been unable to find recorded any case in which similar calcareous deposits were produced. The nearest approach is the case of a child, reported by Berard and Trillat, in which there was urethral tuberculosis and several points were felt which seemed to be due to calcification. Urethral tuberculosis occurs in early childhood and in old age but like all forms of genito-urinary tuberculosis it is most common during the period of sexual activity. Men are affected more frequently than women. Gonorrhœa seems to be a predisposing cause. Several cases of tuberculosis of the glans penis with extension to the urethra have been reported. In cases in which a necropsy has been performed there have been almost without exception other lesions of the genital or urinary tract which appeared to have preceded the urethral lesion. Thus urethral tuberculosis may be secondary to genital or to urinary tuberculosis; usually both tracts are affected. Lesions of the prostate, epididymis, and vesiculæ seminales are nearly always associated. In urethral tuberculosis there are generally two forms of lesion—granulations and ulcers. The former may be grey or yellow. Dr. Chute's case appears to be unique in the fact that the acute stage of the disease ran a favourable course with calcification.

HETEROGENESIS.

THE problem of the origin of life must ever exercise its fascination on the human mind. Since Virgil described the growth of bees from the carcass of a beaten ox to the time when the development of the experimental method led to the researches of Needham and Spallanzani the heterogenetic origin of life has been at intervals the subject of more or less heated controversy. To many the problem would seem to have been solved and most will have forgotten the war which in "the sixties" raged round this and the kindred problem of biogenesis when such champions as Pasteur and Tyndall were ranged against Pouchet and Bastian. Death has removed most of those who then fought but one remains and still upholds the heterogenetic theory. In the *Annals and Magazine of Natural History* Dr. H. Charlton Bastian writes of the origin of bacteria and their allies by heterogenesis and in THE LANCET of Oct. 31st, p. 1220, there is a paper by him on the importance which the proof of this *de novo* origin of micro-organisms has in widening the views on contagion which are current in medical science. In the first mentioned paper, as he says, he has shown that the segments of a rotifer's egg may "presently become alive as amœbæ, monads, peranemata, or even as ciliated infusoria," it would seem comparatively easy to grant that bacteria should have a heterogenetic origin, though owing to their small size the proof may be more difficult. The methods Dr. Bastian employs are reasonings by analogy and experimental investigations on animal and vegetable tissues treated with formalin and kept in vessels washed out with that fluid. Reproductions of photographs of the results of his microscopical examinations are given but though the original sections may carry conviction this is hardly the case with the reproductions. It is, however, well to remember that discussions of this subject have been far from sterile, as in the course of the investigations science and especially bacteriology have been enriched by a large number of practical methods. The second paper deals with the very interesting subject of the origin *de novo* of disease and cites the cases of enteric fever, tubercle, and leprosy as affording evidence of such origin, while the experimental septicæmias produced by the injection of putrid blood or some sterile chemical irritant in the rabbit are held to afford absolute proof that they may originate in this way. When we consider that a pathogenic germ may be so modified that it loses its pathogenicity and becomes indistinguishable from a saprophyte and yet that this same organism may under certain experimental conditions resume its virulence, especially when it is passed through the bodies of extremely susceptible or artificially weakened animals, it is a very tempting hypothesis to suppose that such a disease as typhus fever, which practically never appears except under conditions of starvation or extremely bad sanitation, may be produced by some organism which we usually regard as a saprophyte. In many branches of science, notably in chemistry, it has been by the study of outlying phenomena which did not fall easily within the scope of the current theory that the science has made its next step in advance, and a thoughtful review of some of the outlying phenomena of medicine such as are dealt with by Dr. Bastian cannot fail to be of value. It is of interest, too, to be reminded that the problems of heterogenesis do not in all minds find the same solution and also of the great difficulty, if not impossibility, of finding an absolutely final proof of the biogenetic origin of life.

FISTULA BETWEEN THE PORTAL VEIN AND THE HEPATIC DUCT.

IN the *Australasian Medical Gazette* for September Mr. E. W. Moncrieff, pathologist of Prince Alfred Hospital, Sydney, has reported a remarkable case under the care of Mr. H. V. C. Hinder of fistula between the portal vein and the hepatic duct. An operation for gall-stones was performed on a man and a large calculus was found in the common bile duct. The latter was incised longitudinally. As soon as the calculus was removed there was a gush of blood as if a large vein had been opened. The hæmorrhage was controlled by four forceps which grasped the edges of the incision and finally by means of a large tube stuffed with gauze. A few hours later the movements of the patient displaced the plug and death occurred from hæmorrhage into the peritoneal cavity. At the necropsy the common duct was found to be greatly dilated. It was of about the size of a thumb, its mucous membrane was roughened, and its walls were thickened. The portal vein was quite normal. The gall-bladder was small, shrunken, and thickened, and contained a little mucoid blood-stained fluid. The hepatic ducts were full of dark, clotted blood. At the transverse fissure of the liver the portal vein showed a discoloured patch under the intima about a centimetre in diameter. In this was a small opening with clean cut edges like the mouth of a vein. On introducing a probe the intima was found to be dissected up and the discolouration to be due to effused blood. The probe could be passed on into one of the large hepatic ducts just at its origin from the common duct. Evidently blood had passed directly from the vein into the ducts and escaped when the stone which acted as a plug was removed. On section of the liver all the small bile ducts were found to be full of clots. Microscropic examination of the liver showed an increase of small round cells in the ramification of Glisson's capsule. The cause of the communication between the portal vein and hepatic duct was not obvious. Perhaps the calculus at one time lay over the opening in the hepatic duct and by pressure gave rise to necrosis. The appearance of the blood contained in the ducts was compatible only with recent hæmorrhage, for the clots were soft and dark.

EXPERIMENTAL PSYCHOLOGY AT KING'S COLLEGE, LONDON

THE council of King's College, London, has just elected Dr. C. S. Myers to the lectureship on experimental psychology at the College which was rendered vacant by the resignation of Dr. W. G. Smith who has obtained a similar post at the University of Liverpool. The recently established laboratory devoted to this important branch of science is now in full working order and those who desire to take advantage of it can obtain full particulars by writing to Dr. Myers or to Dr. W. D. Halliburton at King's College.

RECENT ADVANCES IN THE KNOWLEDGE OF GENERAL PARALYSIS.

IN the *Archives de Neurologie* for September a number of communications are published which contain accounts of recent researches made in the pathological histology of general paralysis of the insane by various observers. In the first of these articles Dr. Klippel of Paris gives a lengthy account of his investigations. As the result of his studies he considers that three types of general paralysis, regarded from the pathological standpoint, may be said to exist. The first type is characterised by inflammatory lesions (which may proceed to actual suppuration) of the cerebral meninges and cortex (inflammatory general paralysis). In the second type a lesser degree of meningo-encephalitis is seen, but this is a secondary condition superimposed on a pre existing cerebral degeneration which might have been brought about by other causes to which reference will be made below (associated general paralysis). The third type comprises purely degenerative lesions arising from various causes but unaccompanied by any traces of inflammatory action (degenerative general paralysis). In spite of the attempts of various investigators, says Dr. Klippel, no distinctive histological feature has been found in inflammatory general paralysis which enables us to differentiate it from other inflammations of the brain due to micro-organisms or their toxins, and even the presence of "mast cells" is not pathognomonic of general paralysis. On the other hand, such morbid conditions as cortical hyperæmia with diapedesis of leucocytes, hyaline degeneration of the fine cortical blood-vessels, invasion of the pericellular spaces by leucocytes, and miliary hæmorrhages into the substance of the brain have been described by many observers (Manasse, Klebs, Pierret, and Bischoff) as occurring in the brain as the result of such diseases as chorea, influenza of the "nervous" form, and acute delirium In inflammatory general paralysis there are present such indications of bacterial infection as cystitis and marked leucocytosis. The second type of general paralysis is marked by slight or moderate meningo-encephalitis, due probably to bacterial infection, but supervening on a basis of pre-existing cerebral organic degeneration. Such degeneration has usually been found to be caused by alcoholic indulgence over long periods of time. Patients of this class present signs of fatty and fibroid degeneration in the liver, myocardium, and kidneys. Tuberculosis of chronic and long-standing character produces in some cases a form of special cerebral degeneration on which, as on a basis, the acute infection of general paralysis may develop with facility Similarly brains weakened and altered by the presence and growth of tuberculous tumours or cerebral gummata are prone to suffer from, and succumb readily to, the agencies which produce general paralysis. The third group comprises cases of general paralysis of purely degenerative character, in which the basis is a cerebral debility of congenital origin or one due to tuberculosis or alcoholism of a mild degree of intensity. These cases lapse steadily and uneventfully into dementia with the onset of general paralysis without exhibiting signs of inflammatory or other acute brain mischief. They include the group of cases of the so-called "primarily demented type." Between these three types of cases a few intermediate forms are occasionally met with, so that it is impossible to draw strict lines of demarcation between them. At the acute and rapidly progressive stages of general paralysis, adds Dr. Klippel, acute leucocytosis is observed, the number of polynuclear leucocytes in the blood being high, but during remissions these leucocytes diminish to a normal proportion. Dr. Anglade of Toulouse, in a contribution following the above, stated that lesions of the neuroglia elements in the brain and of the capillaries occurred in the earliest stages of general paralysis. He regarded these changes in the neuroglia and capillaries as primary, and the degeneration of the nerve cell as secondary, phenomena. Lymphocytosis occurred early in the cerebro-spinal fluid—a fact indicating morbid changes in the meninges and blood-vessels. Dr. Laignet Levastine of Paris in another article stated that from a study of 42 brains he had come to the conclusion that the lesions of general paralysis could be classed under the three groups mentioned by Dr. Klippel.

THE ENNO SANDER PRIZE.

THE Association of Military Surgeons of the United States has announced the conditions to be observed by the authors of essays competing for the Enno Sander Prize and it directs special attention to the fact that military and naval medical officers of the British services are eligible. The subject of the competition for 1904 is "The Relation of the Medical Department to the Health of Armies." The conditions of the competition are as *follows* :—

1. Competition is open to all persons eligible to active or associate membership in the Association of Military Surgeons of the United States.

[illegible]

3. In fixing the precedence of the essays submitted the board will take into consideration, primarily, originality, comprehensiveness, [illegible]

[illegible] author. Each one, however, will be authenticated by a *nom de plume*, a copy of which shall, at the same time as the essay, be transmitted to the secretary in a sealed envelope, together with the author's name, rank and address.

[illegible] the successful competitor [illegible] ng annual meeting of the [illegible] erty of the Association of [illegible] and will appear in its publications."

The board of award consists of Lieutenant-Colonel John Shaw Billings, U.S. Army, Brevet-Brigadier-General

George Ryerson Fowler, New York, and Surgeon Henry Gustav Beyer, U.S. Navy. The secretary of the association is Major James Evelyn Pilcher, Carlisle, Pennsylvania, U.S.A. The essayist securing first place will receive a gold medal of the value of $100. The essayist securing second place will receive a life membership in the association of the value of $50.

THE annual general meeting of the Society of the Members of the Royal College of Surgeons of England will be held at the Frascati Restaurant, Oxford-street, on Tuesday, Nov. 10th, at 7 P.M. The meeting will be followed by a dinner at 7.30. Any member wishing to dine will oblige by communicating with the honorary secretary, Society of Members of the Royal College of Surgeons of England, Elmbank, West Hill, Putney, S.W.

THE annual dinner of the staff and past and present students and friends of the Royal Dental Hospital of London will take place on Saturday, Nov. 21st, in the Whitehall Rooms of the Hôtel Métropole under the presidency of Mr. F. J. Bennett, M.R.C.S., L.D.S. Eng. All communications on the subject should be addressed to the Dean at the Royal Dental Hospital, 32, Leicester-square, London.

THE November dinner of the Aberdeen University Club in London will be held at the Trocadéro Restaurant, Shaftesbury-avenue, W., on Wednesday, Nov. 18th, at 7 P.M., Professor George Pirie being in the chair. Members desiring to be present should communicate with the honorary secretaries, Mr. J. Malcolm Bulloch and Dr. Robert J. Collie, 25, Porchester-terrace, W.

THE authorities of Yale University, U.S.A., have invited Dr. C. S. Sherrington, F.R.S., Holt professor of physiology in the University of Liverpool, to succeed Dr. J. J. Thomson, F.R.S., professor of physics in the University of Cambridge, as lecturer under the Silliman Memorial Endowment. The lectures will be delivered at Yale University in the spring of next year.

A GENERAL monthly meeting of the members of the Royal Institution was held on Nov. 2nd, Sir James Crichton-Browne, treasurer and vice-president, being in the chair. Mr. A. K. Huntingdon, Sir Oliver Lodge, Mr. J. Francis Mason, and Mr. Edward H. Woods were elected members.

KING EDWARD VII. SANATORIUM.

HIS MAJESTY THE KING went on Nov. 3rd to Lord's Common, Midhurst, and laid the foundation-stone of King Edward VII. Sanatorium. Special trains from London took down many medical men interested in the open-air treatment of tuberculosis and they were taken to the site from Midhurst and Haslemere stations in brakes, but the steepness of the ascent to Lord's Common rendered the progress of the party very slow, inducing many to proceed to their destination on foot. The sanatorium is placed in park-like grounds at an altitude of about 500 feet. The spot where the buildings will be erected is sheltered by pine trees on rising ground, while the southern aspect is open and affords a charming view over the South Downs towards Chanctonbury Ring. The sanatorium will be built in two portions—an administrative building and a building for the patients. As far as could be made out in the present unfinished state the institution promises to be the most perfect of its kind.

The King arrived at the sanatorium shortly before one o'clock and was immediately conducted by Lord Abergavenny to the pavilion where the foundation-stone was suspended in readiness for the ceremony.

An address was then read by Sir WILLIAM H. BROADBENT, Bart., K.C.V.O., the chairman of the advisory committee. The committee consisted of the following: Sir William Broadbent (chairman), Sir Richard Douglas Powell, Bart., K.C.V.O., Sir Francis Laking, Bart., G.C.V.O., Sir Felix Semon, C.V.O., Sir Hermann Weber, Dr. C. Theodore Williams, Lord Sandhurst, Lieutenant-Colonel Lascelles, Sir Frederick Treves, Bart., K.C.V.O., C.B., and Dr. P. Horton-Smith and Dr. John F. H. Broadbent, secretaries.

THE ADDRESS.

The advisory committee appointed by your Majesty to carry out your Majesty's gracious intention of providing for the open-air and sanatorium treatment of consumption occurring in the classes above the very poor but unable to meet the expense of prolonged residence in private sanatoria, desire humbly to express their satisfaction that the project has reached the stage which offers the occasion for your Majesty's presence here to-day. The site, which after examination of many parts of the country they were able to secure, fulfils in their judgment every requirement for such an institution and they trust that its advantages will be apparent to your Majesty even at this period of the year. The extent of land acquired is 151 acres and was purchased from Lord Egmont. To the south it is open and covered by heather and bracken, while the northern and higher part is well timbered by fine fir-trees. The ground slopes gently to the south, affording a maximum of exposure to the sun; the soil is the lower greensand and the climate particularly suitable. The building will stand at the elevation of nearly 500 feet and will command a view over the valley of the Rother to the South Downs. It will be sheltered from the north and east by a gradual rise of the ground to a height of 630 feet and by beautiful pine woods which will be laid out in walks suitable for the graduated exercise which forms part of the treatment. To the west is an open common with fine views which will be accessible to patients who are convalescent and capable of vigorous exercise. The plans and elevations of the sanatorium as designed by Mr. Percy Adams, the architect, have been submitted to your Majesty. In order that the best principles of construction and management, as approved by the experience of existing sanatoria, and new suggestions in advance of these might be brought to bear upon the institution, your Majesty offered prizes of the value of £500, £200, and £100 respectively for the best essays and plans and with the same object members of the committee and the architect visited sanatoria on the continent and in this country. The part of the building to be occupied by the patients will be a long two-storey building. Each patient will have a separate room and there will be a balcony upon which the patients can sit out or upon which the bed in case of need can be wheeled. For the further enjoyment of open air there will be *Liegehallen* and shelters in the [illegible] ...ds will be 100 and at your Majesty's [illegible] ...een provided for 12 well-to-do patients [illegible] more wealthy classes from the special [illegible] be afforded by the institution. Some delay has been occasioned by difficulties with regard to the water-supply. According [illegible] water of excellent quality was to be found in [illegible] This proved to be the case on bor[illegible] h extremely fine sand which would have interfered with pumping and rendered the supply uncertain. It was therefore necessary to go elsewhere and springs issuing from the same stratum of greensand to the north and capable of supplying 60,000 gallons a day have been secured by purchase from Lord Egmont. The water collected as it emerges from the ground is conveyed to a collecting reservoir near Henley Common and pumped up to a cistern holding 160,000 gallons at the highest point of the site, about 100 feet [illegible] It will thus be available in case of fire as [illegible] of the sanatorium which is estimated at [illegible] The committee desire to tender their humble thanks to [illegible] for the encouragement afforded them in their task and for the interest manifested in the beneficent work placed under their supervision, a striking instance of which is given in your Majesty's presence here to-day. It is their earnest hope that the erection of which your Majesty now lays the foundation-stone may be worthy of the name it will, by your gracious permission, be honoured in bearing—the King Edward VII. Sanatorium.

The KING, in reply, said: My Lords and Gentlemen,—It gives me great pleasure to come here to-day to lay the foundation-stone of my sanatorium for tuberculosis. When a generous donor, whom I regret I am not allowed publicly to thank, placed at my disposal a large sum of money for any philanthropic object which I might have in view I at once decided to devote it to the erection of an open-air sanatorium, having been so greatly impressed with the immense benefit which institutions of this nature conferred on those suffering from pulmonary diseases. It is my hope that by these means the malady may be arrested in the case of not a few of those who would be treated in the institution, while I further trust that on their return home, by diffusing among their relatives and friends a knowledge of the infinite importance of fresh air and sunshine in maintaining health, the conditions under which in so many homes tuberculosis flourished will be sensibly diminished. I note with satisfaction that the site which my committee have secured fulfils all the essential requirements of a sanatorium, and I trust that the sandy soil, the southern aspect, and the pine trees which give protection from the north and the east will assist in restoring health to the inmates of the institution. I am aware that this site has not been chosen without investigating many others, and I thank my committee, and especially among them Dr. Theodore Williams, for the many visits which they have paid to other possible sites in various parts of England You, Sir William Broadbent, have alluded to the difficulty experienced in obtaining a satisfactory supply of water and to the delay which has in consequence been caused in commencing the building of the institution This was unavoidable, for without a proper supply of water an otherwise excellent site becomes valueless I am glad now to know that through the ingenuity and skill of Mr Brough Taylor all difficulties have been overcome and that an ample supply of absolutely pure water has been obtained. I observed with satisfaction in driving here the condition of the road leading to the institution, which has recently been constructed The great rapidity with which this has been completed, under the supervision of Messrs John Aird and Sons, is, I hope, an earnest of the way in which the building of the sanatorium itself will be pushed forward now that all preliminary difficulties have been overcome You have alluded in general terms to the character of the building which will be erected As you have rightly stated it will be for the accommodation not of the very poor—they are already being provided for—but of those of slender means who are unable to meet the expenses of prolonged residence in private sanatoria A certain number of beds will also be reserved for more wealthy patients I am glad to know that while no necessary comforts which will aid to the well being of the patients will be omitted there will be a total absence of all luxury and of expenditure of money on superfluous appointments I regret that it was not possible for the Queen to accompany me here to day Like myself, she is deeply interested in the fight against tuberculosis and has proved it by permitting the Queen Alexandra Sanatorium at Davos to be called by her name We both of us pray that the institution of which I am about to lay the foundation stone may receive the blessing of God and that those who come to reside here may find renewed health and strength to enable them to carry out their duties in the world

The Bishop of CHICHESTER then conducted the religious service and the stone was declared to be well and truly laid by the King

His Majesty before leaving spent some time conversing with the members of the advisory committee and recognised one or two of the general company present

TRANSVAAL ADMINISTRATION REPORTS FOR 1902

PUBLIC HEALTH DEPARTMENT

OUT of a volume consisting of 264 pages of Blue book dimensions 28 are devoted to the report of the health of the Transvaal during 1902 Dr George Turner, medical officer of health of the Transvaal, laments the impossibility of getting a trustworthy report owing to insufficiency of returns, statistics, &c This can be readily understood when it is remembered that up to June 1st, 1902 warlike operations were still in progress The group of diseases classed together as "typhus typhoid enteric gastric, or typho malarial fever" accounted for 194 deaths out of a total of 2906 patients under observation Of the 194 deaths 78 were of white people and 116 were of coloured Dysentery claimed the largest number of victims, however, amounting to 228 out of the total of 2906 Malaria accounted for only 17 deaths One death only from scarlet fever is recorded and six from measles Classified with small pox and chicken pox we find the unfamiliar term of "amaas" a term which no doubt has a local meaning but is not included amongst the official nomenclature of diseases and therefore requires explanation In the leper asylum at Pretoria there were 230 leper patients on Dec 31st, 1902, being an increase of 14 upon the number resident in the asylum on Jan 1st, 1902. Dr Turner states that it is very doubtful if heredity plays any part in causing leprosy, that leprosy is conveyed in some way by contagion is incontestable, and that in the Transvaal there is not a particle of evidence that fish in any way influences the spread of the disease As regards vaccination the result of experience in the Transvaal is summed up thus "I am by no means impressed with the desirability of using calf lymph. I am of opinion that arm to-arm vaccination is more efficient and when properly carried out is perfectly safe"

An excellent report by Mr R Fox Symons, medical officer of health of Pretoria and district, specifies the causes of deaths registered in his district during the year 1902, and shows that of 486 deaths 51 persons died from dysentery and 29 from enteric fever Pneumonia caused 57 deaths and enteritis 61 The high percentage of deaths due to intestinal ailments, enteric fever, enteritis, and dysentery, was the most striking feature of the report

Mr C L Sansom medical officer of health of the Witwatersrand district, divides his report for the year into two, the first part ending June 30th, 1902 In almost all districts he comments on the unsatisfactory condition of the water supply

At the bacteriological laboratory at Daspoort, under the direction of Dr Theiler, valuable work was done in prosecuting the study of horse sickness, the so called Rhodesian red water disease amongst cattle, rinderpest and biliary fever in horses Trypanosomiasis was also studied and Dr Theiler states that a fly belonging to the genus hippobosca was responsible for the spread of the disease

Mr W C C Pakes during the year 1902 examined 860 specimens sent to him at the Government laboratories for analysis Of these 805 required chemical investigation, 16 toxicological examination, and 39 bacteriological examination

The Transvaal medical department, although not by any means completed seems to be rapidly becoming organised, and on the basis of the work indicated in this report we look forward to many valuable additions to our knowledge in the near future

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN ordinary Comitia was held on Oct. 29th, Sir WILLIAM S CHURCH, Bart, K C B, the President, being in the chair

The following gentlemen having passed the required examination were admitted as Members Dr Sydney Walter Carl, Dr Charles Edwin Percy Forsyth, Dr James Edward Hill Sawyer, Dr Jacob Snowman, and Dr James George Taylor

Licences to practise were granted to 102 gentlemen who had passed the required examinations

The PRESIDENT announced that Mr Arthur Richardson, late of Epsom College, had been appointed Jenks scholar for the ensuing year He also announced that he had nominated Dr T H Green, Dr E C Seaton, and Dr F J Wethered to be adjudicators of the Weber Parkes prize and medals at the next award in 1906

The PRESIDENT also asked the permission of the College to permit Sir Hermann Weber to deliver a lecture at the College on a date to be announced on Measures for prolonging Life The request was granted

The following communications were received 1 From the Board of Trade, forwarding a translation into English of a report by a Norwegian committee respecting beri beri occurring on European sailing ships A committee was appointed to consider the report consisting of the President, Sir Patrick Manson, and Dr J F Payne 2 From the secretary of the Royal College of Surgeons of England reporting certain proceedings of its Council on August 4th and Oct 15th 3. From the Society of Arts inviting the College to form with it a joint committee for advising on the award of the Swiney Prize in January next The officers of the College were appointed to serve on the committee 4 From Professor Silvanus Thompson on the approaching tercentenary of the death of Sir William Gilbert, President of the College in 1600 The treasurer and senior censor (Sir Dyce Duckworth) Dr W H Allchin, and Dr J Abercrombie were appointed to act on any committee which might be formed to carry out suitable arrangements to mark the occasion

The audited accounts for the year ending Sept 29th last were received and adopted.

The quarterly report of the Finance Committee was received and adopted

A report from the Committee of Management dated Oct 5th was received and adopted. The committee recommended that Cranbrook School should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and practical chemistry

Dr. Norman Moore was re-elected a member of the Committee of Management. A report from the Laboratories' Committee dated Oct. 9th was received and adopted and Dr. Sidney Martin was re-elected a member of that committee.

A list of books and other publications presented to the library during the past quarter was received and the thanks of the College were returned to the donors. After some formal business the President dissolved the Comitia.

UNIVERSITY OF LONDON.

A MEETING of the Faculty of Medicine was held at the University, South Kensington, on Oct. 30th. Mr. H. T. BUTLIN, the Dean of the Faculty, presided and there were 41 members present.

Sir Isambard Owen was re-appointed Vice-Dean, and Dr. Lauriston Shaw honorary secretary, for the ensuing year.

Certain communications from the Royal Veterinary College, from the Board of Agriculture, and from the Royal Agricultural Society with regard to the institution by the University of a degree in veterinary science were considered by the faculty. It was resolved:—

> That in the opinion of the Faculty of Medicine it is desirable to encourage the teaching and study of veterinary science within the University.

The reports of the several boards of studies comprised within the faculty as to their composition for the ensuing year were considered and with slight modifications were approved.

A report from the board of intermediate medical studies upon the arrangements for the special examinations in organic chemistry in 1904 which had been rendered necessary by the recent modifications in the curriculum was considered and approved.

A report was received from the board of intermediate medical studies defending the recent alterations in the curriculum so far as they concerned the teaching and examination in chemistry. The faculty resolved to refer this matter to a special committee for consideration and report. The committee was constituted as follows:—Dr. J. R. Bradford, Mr. H. T. Butlin, Dr. F. D. Chattaway, Mr. A Pearce Gould, Dr. W. D. Halliburton, Dr. H. W. G. Mackenzie, Dr. Norman Moore, Sir W. Ramsay, Professor A. W. Reinold, Dr. W. G. Ridewood, Mrs. M A. D. Scharlieb, Mr. S. G. Shattock, Dr. Lauriston E. Shaw, and Professor G. D. Thane.

ASYLUM REPORTS.

Dorset County Asylum (Annual Report for 1902).—The average number of patients resident during the year was 737—viz, 355 males and 382 females. The admissions during the year amounted to 156, comprising 77 males and 79 females. Of these 130 were first admissions. Dr. P. W. Macdonald, the medical superintendent, states in his report that the unfavourable nature of a number of the admissions was shown by the fact that many of the patients were aged and feeble and others greatly reduced in physical strength. Referring to an undesirable class of patient among the admissions Dr. Macdonald writes: "Another class of patient ...... was in strong evidence among the admissions in 1902, I mean the 'jail bird.' These men are often the lowest of the low and neither attention nor persuasion has the least influence in improving or altering their ways. When, as generally happens, they are evilly disposed and maliciously inclined, then their care and treatment become indeed trying and difficult When this class of patient is a fairly educated being ...... his method of influencing others, his persistent, unfounded complaints and studied abuse are a source of trouble and worry far beyond the ordinary class of patient." Two causes, heredity and worry, apparently overshadow all other causes and remain closely linked together in the production of insanity. The number of patients discharged as recovered during the year amounted to 38—viz, 17 males and 21 females, or 5·1 per cent. of the average number resident. The deaths during the year amounted to 60—viz, 35 males and 25 females, or 8·1 per cent. as calculated on the same basis. Of the deaths two were due to renal disease, three to cerebral degeneration, four to pulmonary tuberculosis, eight to cardiac disease, nine to general paralysis of the insane, 10 to senile decay, 12 to pneumonia and broncho-pneumonia, and the rest to other causes. Table 22 of the last census returns for the county of Dorset states that the county has sustained a net loss by migration of 10,171. "This excessive drain on the population has an important bearing on the high rate of lunacy in the county." The Commissioners in Lunacy state in their report that all parts of the asylum continued to be maintained in excellent order, that the wards were bright, cheerful, and plentifully supplied with objects calculated to interest the patients, that the dormitories without exception were sweet and clean, that the bedding was in a very satisfactory condition, that the private patients were very comfortably lodged in special wards, that the personal condition and dress of the patients were satisfactory, and that the medical case books and records were very well kept. The committee of management states in its report that a new building, at an estimated cost of £39,500, is in course of erection for the admission of private patients. The weekly rate of maintenance per patient has remained at 9*s.* 4*d.* throughout the year. The committee reports very favourably upon the general efficiency of the officers and staff of the asylum.

Nottingham City Asylum (Annual Report for 1902).—The average number of patients resident during the year was 750, comprising 374 males and 376 females. The admissions during the year amounted to 184—viz., 89 males and 95 females. Of these 169 were first admissions. Mr. Evan Powell, the medical superintendent, states in his report that with regard to the causes of insanity in the cases admitted intemperance in drink heads the list, and it is noted "that the cases from this cause are practically in equal proportions of the sexes, which is quite unusual in the general statistics of the country. Side by side with this fact it is of interest to find that a much larger proportion of females to males are found to be suffering from general paralysis [of the insane] here than in other places which leads to the belief that there is a closer connexion between drink and this disease, as cause and effect, than is now admitted." Hereditary predisposition to insanity was found to be present in a large proportion of cases and influenza has been the cause of insanity in a few. The number of patients discharged as recovered during the year amounted to 60—viz., 33 males and 27 females, or 8·0 per cent. of the average number resident. The deaths during the year amounted to 72, or 9 6 per cent as calculated on the same basis. The recovery-rate, adds Mr. Powell, may be considered satisfactory "considering the very large proportion of hopeless cases admitted." The death-rate was rather below the average of previous years. All the deaths were from natural causes and there was no occasion for holding an inquest. There was only one serious accident during the year—in the case of a male patient who accidentally fell and received a fracture and dislocation of the ankle. There were only three cases of infectious fever during the year—viz., one of scarlet fever and two of typhoid fever. All made good recoveries and there was no spread of the disease from any of the cases. The Commissioners in Lunacy state in their report that both divisions of the asylum were in excellent order, that the patients of both sexes were neatly dressed and well behaved, that the sleeping rooms and bedding were thoroughly clean and sweet, and that the medical records and case-books were carefully and intelligently kept. They point out that post-mortem examinations were made in the very creditable proportion of 97 per cent of cases of death. The committee of management states in its report that the weekly charge of maintenance per patient has remained at 10*s*, that the accommodation within the asylum is now sufficient for the requirements of the city, that the profit derived from the maintenance of out-county patients has enabled the whole of the cost of repairs and upkeep of the building to be met, and that it has not been found necessary to go to the finance committee for the sum estimated, and provided, for that purpose at the beginning of the year. The committee has visited the asylum every fortnight and when practicable has visited the wards and seen the patients and has been quite satisfied with the condition of the wards and the care and comfort of the patients.

Belfast District Asylum (Annual Report for 1902).—The average number of patients resident during the year was 956, comprising 458 males and 498 females. The admissions during the year amounted to 267—viz., 116 males and 151 females; of these, 231 were first admissions. Dr. William Graham, the medical superintendent, states in his report that although the usual categories under which the causation of insanity is divided are heredity, drink, business anxieties, unhygienic conditions, and intermarriage, it ought to be known that modern science penetrates behind these specific causes to a theory of causation in general. "Briefly put, that theory is that certain forms of *insanity are largely the result of various toxins or poisons* acting on the nerve cells of the brain and nervous system which are associated with intellectual functions. These poisons may come from without, such as alcohol or morphine, or they may be generated from within through defective nutrition and other causes. When we speak of insanity being hereditary ...... what we mean is that certain nerve cells in certain persons have a special susceptibility to these poisonous influences." But we are as yet, continues Dr. Graham, too ignorant of the conditions under which the laws of predisposition operate to know whether one day we may not be able to control the hereditary transmission of the insanities. However, there are causes palpably at work which are absolutely under our control. "It is not too much to assert that half the existing insanity could be banished or contracted to inconsiderable limits were the hygienic conditions in the home, the school, and the factory what they ought to be." The number of patients discharged as recovered during the year amounted to 74—viz., 29 males and 45 females, or 7·8 per cent. of the *average number resident. The deaths during the year* amounted to 79, or 8 25 per cent. as calculated on the same basis. Of the deaths three were due to cardiac disease, five to renal disease, six to pulmonary and other forms of tuberculosis, seven to epilepsy, ten to senile decay, 15 to general paralysis of the insane, and the rest to other causes. "General paralysis of the insane claimed more victims this year than last. This unhappy state of affairs is, however, universal and is largely due to the greater stress and excesses of modern life." The general *health of the inmates has been good throughout the year* though the asylum has been overcrowded. The Inspector of Lunatics states in his report that the wards were bright and well ventilated, that the dietary of the patients was satisfactory, that all parts of the asylum were in good order, and that the medical case-books and records were well and carefully kept. A slightly increased cost of maintenance prevailed during the year, being due to exceptional expenses in connexion with the repair of the asylum.

Looking Back.

FROM

THE LANCET, *SATURDAY*, NOV. 5, 1825.

FOREIGN DEPARTMENT.

Rheumatic Gout cured by Acupuncturation.

M. Andrieux, in the *Bulletin de l'Athenée*, gives the case of a man, aged 49 years, who, during the last 10 years, had suffered from attacks of gout in the knees, elbows, wrists, and the articulations of the fingers, which were permanently deformed. In December last the right foot became red, swelled, and extremely painful; a needle was inserted at the origin of the little toe, and brought out under the malleolus externus. The needle was no *sooner inserted than the patient felt himself relieved; he* could move his foot and suffer it to be touched, whereas before the slightest motion was insupportable. Fearing a return of the pain, M. Andrieux introduced a second needle below the malleolus internus; at the end of ten minutes the needles were taken out; they were considerably oxydized. The patient could rest his foot upon the ground and walk with ease, whereas a quarter of an hour before he could not bear the mere contact of the blankets. M. Andrieux thinks that the electrical equilibrium which the needles establish between all the parts, is the cause of the success which attends acupuncturation. The opinion of M. Andrieux, on this point, is entitled to the more attention as he has devoted much of his attention to the influence of galvanism on the animal economy, and has, in many instances, applied this agent to therapeutics with the most successful results.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8812 births and 4718 deaths were registered during the week ending Oct. 31st. The annual rate of mortality in these towns, which had been 15·8, 15·8, and 15·9 per 1000 in the three preceding weeks, further rose last week to 16 3 per 1000. In London the death-rate was 15·8 per 1000, while it averaged 16·5 in the 75 other large towns. The lowest death-rates in these towns were 4 7 in Hornsey, 6 9 in Reading, 8·3 in Leyton, 9·9 in Southampton, 10·0 in Croydon, 10 2 in Hastings, and 10 4 in East Ham and in Newport (Mon.); the highest rates were 21·0 in Wigan and in Oldham, 21 8 in South Shields, 22 0 in Walsall, 22 1 in Rochdale, 23·3 in St. Helens, 24 6 in Rotherham, and 29·9 in Warrington. The 4718 deaths in these towns last week included 523 which were referred to the principal infectious diseases, against 704, 635, and 532 in the three preceding weeks; of these 523 deaths, 250 resulted from diarrhœa, 74 from measles, 61 from diphtheria, 53 from "fever" (principally enteric), 41 from whooping-cough, 40 from scarlet fever, and four from small-pox. No death from any of these diseases was registered last week in Hornsey, Bournemouth, Reading, Northampton, Smethwick, or Coventry, while they caused the highest death-rates in Great Yarmouth, Hanley, Wigan, Warrington, Preston, Rotherham, Sunderland, Gateshead, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Warrington, Bury, Preston, Rotherham, and Sunderland; from scarlet fever in Devonport and Walsall; from diphtheria in Portsmouth, Walsall, and York; from whooping-cough in Wigan, Rochdale, and Merthyr Tydfil; from "fever" in Walsall and Merthyr Tydfil; and from diarrhœa i[illegible] ham, and [illegible] registered [illegible] one in St[illegible] towns. The number of small pox cases under treatment in the Metropolitan Asylums hospitals, which had been 17, 11, and 34 on the three preceding Saturdays, had further risen to 42 on Saturday last, Oct. 31st; 12 new cases were admitted last week, against two, one, and 26 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1828, against 1881, 1861, and 1858 at the end of the three preceding weeks; 199 new cases were admitted during the week, against 240, 208, and 209 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 146, 175, and 194 in the three preceding weeks, further rose to 260 last week, but were 32 below the number in the corresponding period of last year. The causes of 57, or 1·2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Bradford, Leeds, Newcastle-on-Tyne, and in 46 other smaller towns; *the largest proportions of uncertified* deaths were registered in Hanley, Smethwick, Liverpool, Bootle, St. Helen's, Manchester, Salford, Barrow-in-Furness, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·0, 16·1, and 16·7 per 1000 in the three preceding weeks, further rose to 17·0 *per 1000* during the week ending Oct. 31st, and was 0·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 14·4 in Leith and 14·9 in Edinburgh to 20 1 in Perth and 22 0 in Paisley. The 557 deaths in these towns included 33 which were referred to diarrhœa, 11 to measles, seven to whooping-cough, five to diphtheria, four to scarlet fever, and two to "fever," but not one to small-pox. In all, 62 deaths resulted from these principal infectious diseases last week, against 71, 72, and 77 in the three preceding weeks. These 62 deaths were equal to an annual rate *of 1 9 per 1000*, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 41, 35, and 39 in the three preceding weeks, further declined last week to 33, of which

17 were recorded in Glasgow, six in Dundee, three in Edinburgh, two in Aberdeen, two in Paisley, and two in Greenock. The deaths from measles, which had been eight, 14, and 16 in the three preceding weeks, declined again to 11 last week, and included nine in Glasgow. The fatal cases of whooping-cough, which had been six, seven, and eight in the three preceding weeks, decreased again last week to seven, of which three occurred in Glasgow. The deaths from diphtheria which had been four in each of the two preceding weeks, rose to five last week, and included two in Glasgow. The four fatal cases of scarlet fever corresponded with the number in the preceding week and included two in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 62, 82, and 92 in the three preceding weeks, further rose last week to 108, but were 38 below the number in the corresponding period of last year. The causes of 18, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·7, 18·6, and 21·5 per 1000 in the three preceding weeks, declined again to 21·2 per 1000 during the week ending Oct 31st. During the past four weeks the death-rate has averaged 21·2 per 1000, the rates during the same period being 15·2 both in London and in Edinburgh. The 154 deaths of persons belonging to Dublin registered during the week under notice showed a slight decline from the number in the preceding week and included seven which were referred to the principal infectious diseases, against nine nine, and 13 in the three preceding weeks; of these, four resulted from diarrhœa, two from whooping-cough, and one from scarlet fever, but not any from small-pox, measles, diphtheria, or "fever." These 7 deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·6 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had been four, five, and eight in the three preceding weeks, declined again last week to four. The 154 deaths in Dublin last week included 34 of children under one year of age and 36 of persons aged 60 years and upwards; the deaths of both infants and elderly persons showed a slight decline from the respective numbers in the preceding week Eight inquest cases and six deaths from violence were registered, and 67, or nearly 44 per cent., of the deaths occurred in public institutions. The causes of 11, or more than 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following civil practitioners have been appointed Surgeons and Agents:—G. Myles, at Limerick; J. E. Hibbert, at Penarth; S. E. Martin, at Newry; P. L. Watkin Williams, at Bridgwater; H. M. Hughes, at Stockton; and P. Aitken, at Bo'ness (dated Oct. 27th, 1903).

ROYAL ARMY MEDICAL CORPS.

Captain H. V Prynne is appointed specialist in ophthalmology in the Thames and Woolwich Districts.

Lieutenant Colonel W. O. Wolseley to be Colonel, vice W. L. Gubbins, promoted (dated August 27th, 1903). Lieutenant-Colonel A. T. Sloggett, C.M.G., to be Colonel, vice W. B. Allin, deceased (dated Sept. 9th, 1903).

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service made by the Government of India:—To be Colonel: Lieutenant-Colonel (temporary Colonel) Thomas James Hackett Wilkins (dated June 30th, 1903). Captains to be Majors (dated July 28th, 1903): *Bengal Establishment:* Benjamin Hobbs Deare, Benjamin Curwen Oldham, Robert Bird, Sidney Browning Smith, John Stuart Shepherd Lumsden, George Hewitt Frost, Edmund Wilkinson, George Francis William Ewens, Charles Duer, and Henry Stotesbury Wood. *Madras Establishment:* James Entrican, Walter George Pridmore, Charles Donovan, Jeremiah Penny, Douglas Henry McDonell Graves, and Charles Henry Leet Palk. *Bombay Establishment:* Thomas Walter Irvine.

The King has also approved of the retirement from the service of the undermentioned officers:—*Bengal Establishment:* Lieutenant-Colonel Samuel Ferguson Bigger (dated Sept. 1st, 1903); Major Basanta Kumar Basu (dated August 21st, 1903).

The following appointment has been made to the Staff in India:—Major W. H. W. Elliott, D.S.O., to be secretary to the Principal Medical Officer, His Majesty's Forces in India, vice Lieutenant-Colonel J. Shearer, D.S.O., vacated (dated August 13th, 1903).

IMPERIAL YEOMANRY.

Royal 1st Devon: Francis Ernest Little to be Surgeon-Lieutenant (dated Oct. 31st, 1903). Duke of Lancaster's Own: Surgeon-Lieutenant-Colonel W. W. Wingate Saul retires under the provisions of paragraph 54 Yeomanry Regulations, and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform on retirement (dated Oct. 31st, 1903). 3rd County of London (Sharpshooters): Surgeon-Lieutenant E. M. Rooke resigns his commission (dated Oct. 31st, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Aberdeenshire: Surgeon-Lieutenant H. McI. W. Gray to be Surgeon-Captain (dated Oct. 31st, 1903). The Highland: Charles Gordon Mackay, late Lieutenant, to be Surgeon-Lieutenant (dated Oct. 31st, 1903).

Rifle: 1st Surrey (South London): Daniel Oliver Kerr to be Surgeon-Lieutenant (dated Oct. 31st, 1903).

Correspondence.

"Audi alteram partem."

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—Will you allow me to supplement Sir William Broadbent's appeal for the British Medical Benevolent Fund (to which I am a subscriber) by pointing out that no practitioner residing within 20 miles of London ought to, or need, leave his widow and orphans unprovided for if he will but join the Society for the Relief of Widows and Orphans of Medical Men, and pay one guinea subscription half-yearly up to the time of his decease. The office of the society is at 11, Chandos-street, Cavendish-square, W.

I am, Sirs, yours faithfully,
CHRISTOPHER HEATH, F.R.C.S. Eng.,
President of the Society.

Cavendish-square, W., Oct. 31st, 1903.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—I am obliged to Dr. A. G. Auld for his courteous and interesting reply to my criticisms on his letter to THE LANCET of Oct. 17th, p. 1118. May I say that I have an entirely open mind as to the existence of a pulmonary reflex and that I was prompted to write simply because the evidence adduced by Dr. Auld in favour of such a reflex did not appear to me to be conclusive; nor do I find the fresh evidence he advances in his second letter wholly convincing. Dr. Auld points out that the thoracic expansion which results from protracted rubbing of the chest or vigorous percussion of the epigastrium persists longer than that which follows upon the voluntary taking in of deep breaths, from which he argues that the expansion in the former case is not due to the deep breaths which he admits are induced by the stimuli referred to and must therefore result from a reflex bronchial dilatation. May we not, however, explain the longer duration of the expansion in that case on the assumption that in it some degree of dyspnœa is induced, while in the latter case the very opposite condition of apnœa is brought about?

The other evidence advanced by Dr. Auld, though of a more convincing kind, is yet open to criticism. He points to the facts that the spraying with ether or the long-continued percussion of the chest over a collapsed pulmonary base causes a local (as against a general) expansion of the lung; but is it not possible that these stimuli thus locally applied may excite the local inspiratory muscles more than the others? The sudden application of cold to the chest, for example, is known to excite inspiration and tends, I suggest, when applied to one side to cause it to *expand more than the other.* In regard to the thoracic expansion said to follow upon the absorption into the blood of such drugs as atropine and hyoscine I would ask whether, even granting its origin in bronchial dilatation, we can justly refer to it as an example of genuine reflex action?

The remaining portion of Dr. Auld's second letter touches a side issue raised by myself. Assuming the existence of a reflex bronchial dilatation, how is the thoracic expansion resulting from it effected? In criticising my explanation of this expansion Dr. Auld unwittingly fails to do me justice. He says that in making "the general assertion" that whatever thoracic enlargement results from reflex bronchial dilatation is *chiefly* effected by the inspiratory muscles I "fail to appreciate" the fact that the chest tends to recoil outwards when pulmonary suction is diminished; it is, however, clear from the employment of the italicised word that I admitted the operation of some other factor, and in point of fact the other factor I had in mind is the very one for which Dr. Auld calls me to task for neglecting; for in an earlier part of my letter I say "the primary effect of bronchial dilatation must be to cause a relaxation of pulmonary tissue and thus, by diminishing the suction action of the lungs on the thoracic walls and diaphragm, somewhat to increase the size of the chest cavity"—i e., by passive outward recoil. I then go on to observe that the thoracic expansion would not end here but that the inspiratory muscles would come into augmented action so as to tone up the relaxed pulmonary tissue to the norm, and that throughout life "the inspiratory muscles are ever busy keeping the lungs at the requisite degree of stretch." Dr. Auld does not accept this proposition. As I believe it to express an important principle in thoracic physics I shall be grateful to you, Sirs, if you will afford me this opportunity of vindicating it.

All will agree that pulmonary suction is not a merely accidental phenomenon but that, on the contrary, it serves some useful purpose or purposes, and such being the case we may be sure that the organism will strive to maintain it at the requisite level. I contend that this end is achieved by the inspiratory muscles. We shall, I think, be helped to an understanding of this position by inquiring into the origin— [illegible] ulmonary suction. Before birth [illegible] upon their solid and liquid contents; at birth the thorax is expanded by the inspiratory muscles and air thus sucked into the lungs. Now it might conceivably happen that just sufficient thoracic expansion is effected at birth to open all the tubes and vesicles of the lung *without putting the pulmonary tissue on the stretch*—without, that is, inducing pulmonary suction—and such is possibly the case for a short time after birth. Very soon, however, the chest is expanded beyond this point, the pulmonary fibres being actually stretched, and in this way pulmonary suction is gradually established. Now I can conceive of no other means by which this stretching can be effected than by the action of the inspiratory muscles, and my contention is that these muscles are throughout life ever on the watch to maintain pulmonary suction at its proper level. It is true that after the first months—perhaps I should say years—of post partum life pulmonary suction operates even at the end of an ordinary expiration, when, i.e, there *is little or no active contraction* of the inspiratory muscles, a fact which is shown by the thoracic expansion which takes place in the cadaver after puncturing the pleuræ and thus allowing the lungs to collapse; but this, I would observe, is because the inspiratory muscles having through a long period kept the chest expanded beyond the point at which suction first appears the chest has become "set" in this position—to wit, in the neutral position referred to—one, namely, corresponding (about) to the position of the chest at the end of an ordinary inspiration. This "setting" of the chest in the "neutral" position undoubtedly helps to relieve the inspiratory muscles in their function of maintaining pulmonary suction at the norm; nevertheless we shall find if we look at the matter more closely that this function belongs essentially to the inspiratory muscles.

In the first place, the ne[illegible] by the shortening of the [illegible] action preponderating ove[illegible] Then there is the fact that in widespread paralysis of the inspiratory muscles, such as may, for example, occur in idiopathic muscular palsy, the chest tends to collapse and in some cases (especially in young subjects) this happens to such an extent as to lead, I can have no doubt, to the entire disappearance of pulmonary suction. What could better show the ultimate dependence of this latter upon the inspiratory muscles? Finally, I would in this connexion draw attention to the fact that the neutral position of the chest is liable to great modification through the forcible action of the inspiratory muscles. Consider, for example, what great permanent expansion can be effected in the contracted chests of sedentary youths by suitable exercises and the steady augmentation in the size of the thorax which takes place in hypertrophous emphysema. In both cases a shifting of the neutral point occurs and there can be no doubt that this is effected by an augmented action of the inspiratory muscles.

I conclude, therefore, that pulmonary suction is essentially dependent upon the action of these muscles and if I have satisfactorily established this conclusion I have proved the thesis "the inspiratory muscles are ever busy keeping the lungs at the requisite degree of stretch"; for if it is of great moment (and who can doubt it is?) that the organism shall maintain pulmonary suction at the norm we may be quite sure that it will avail itself of the only means at its disposal for achieving this end—i.e., the action of the inspiratory muscles. Many instances can be cited of the inspiratory muscles coming into extra action for the purpose of raising pulmonary suction to the normal level. Perhaps the most interesting is the case of hypertrophous emphysema already referred to. I am pleased to find Dr. Auld accepting my view that one of the reasons why the chest enlarges in this affection is in order to tone up the relaxed pulmonary fibres. Another instance is afforded by the case of a large pleural effusion under negative pressure; in this case we may find considerable expansion of the thorax; such expansion is manifestly brought about by the inspiratory muscles and has for one of its objects the maintenance of the normal pulmonary suction which otherwise would stand in danger of disappearing altogether. It is now, I trust, clear why in my former letter I concluded that, given considerable relaxation of the bronchial muscles, the inspiratory muscles will come into extra action in order to tighten up the relaxed pulmonary tissue, for otherwise pulmonary suction must necessarily fall below the norm.

What purpose or purposes, I am tempted to ask in conclusion, are served by pulmonary suction? Though doubtless it helps breathing by promoting the upward movement of the diaphragm I can have little doubt that its essential function is to facilitate cardiac diastole, notably the diastole of the auricles and of the right auricle in particular. Nature has, in fact, cunningly placed the heart in a partial vacuum, from which I conclude that the inspiratory muscles take no small share in aiding cardiac diastole and in this way favouring the return of blood to the heart. Apologising for the length of this letter,

I am, Sirs, yours faithfully,
Wimpole street, W., Nov. 1st, 1903. HARRY CAMPBELL.

KING'S COLLEGE HOSPITAL REMOVAL FUND.

To the Editors of THE LANCET.

SIRS,—As already reported in THE LANCET,[1] at a meeting of the governors held on Oct. 12th, 1903, it was finally decided to remove King's College Hospital from its present position to a site in South London. The main object of the removal is more fully to carry out the idea of the charity by transferring it from a district largely denuded of its poor inhabitants to one in which there is a dense population urgently in need of hospital accommodation. By the removal this urgent need which has long existed in South London will be met without the addition of another large general hospital to those at present existing, most of which already have a constant struggle in meeting their necessary expenditure.

The governors when sanctioning the present course authorised the joint committee appointed by the council of King's College and the committee of management of the hospital to act for them in all matters appertaining to the removal. In accepting this authority the committee are fully conscious of the great responsibility they have taken upon themselves and they are determined jealously to guard the traditions of the charity and the many benefactions made to it. A sum of not less than £300,000 will be required to build and to equip the hospital, so as to enable it to meet the needs of the three-quarters of a million of population who will be benefited by the removal.

---

[1] THE LANCET, Oct. 17th, 1903, p. 1110.

The committee now appeals to the public for help towards raising this required sum and it feels confident that it will not appeal in vain. The committee is allowed to add that this appeal is issued with the approval of His Royal Highness the Duke of Cambridge, President of the hospital. It also has the cordial support and hearty approval of His Grace the Archbishop of Canterbury, one of the Vice-Presidents of the hospital and visitor of the College. A suitable site of 12 acres in South London has been presented to the hospital by the munificence of a single donor.

It remains but to say that donations to the Removal Fund will be thankfully received by the treasurer, Mr. Charles Awdry, 2, Hyde Park-street, W.; by Lloyd's Bank, Limited, Law Courts Branch, 222, Strand, bankers to the hospital; and at King's College, Strand, by Mr. A. MacLeod Forest, the secretary King's College Hospital Removal Fund.

We are, Sirs, yours faithfully,
W. F. D. SMITH,
Chairman of the Joint Committee Removal of King's College Hospital.
METHUEN, Lieutenant General,
Chairman of the Hospital Committee.
E. S. ROFFEN.
LISTER,
Vice-President and Consulting Surgeon of the Hospital.
CHARLES AWDRY,
Treasurer.
ARTHUR C. HEADLAM,
Principal of King's College.
DAVID FERRIER,
Senior Physician of the Hospital.
W. WATSON CHEYNE,
Senior Surgeon of the Hospital.

PHIMOSIS AND CANCER OF THE PENIS.

To the Editors of THE LANCET.

SIRS,—In a letter in THE LANCET of August 8th, p. 423, it is contended that phimosis is not a potent cause of cancer of the penis. This perhaps may be the case in simple phimosis but it is surely not so (at any rate in this country) if the phimosis becomes complicated with venereal disease. During the last five years 25 cases of cancer of the penis have come under my observation—18 were submitted to operation, while seven were inoperable owing to too advanced growth. At least 15 of these cases gave a similar history: an original phimosis, some venereal trouble, chronic discharge from the preputial orifice, increasing pain and swelling, and finally perforation of the prepuce and protrusion of the growth. It must, of course, be taken into consideration that these cases were absolutely untreated from the beginning and the disease was allowed to take its course unchecked. It may be noted that phimosis is rare, while cancer of all kinds is uncommon. Sections of the 18 cases operated upon were examined, the growth in all cases being a squamous epithelioma.

I am, Sirs, yours faithfully,
Seoul, Corea, Sept. 20th, 1903. EDWARD H. BALDOCK.

THE TREATMENT OF GOITRE BY THE USE OF DISTILLED OR RAIN WATER.

To the Editors of THE LANCET.

SIRS,—In reference to the above I should like to put on record four cases under my care in this district. Although this communication tells against the usefulness of the method and must necessarily reach you very long after the already published facts, yet it is so extremely important for all aspects of a treatment to be impartially set forth that I venture to send you the following notes.

Outtrim is a colliery district in South Gippsland, Victoria, quite close to the extreme south-east corner of the continent. It supports about 2600 inhabitants and is very hilly. The whole water-supply consists of rain water collected on galvanised-iron roofs and stored in galvanised-iron tanks and is from my own analysis of excellent quality. It is true that some underground tanks exist in which rain water is stored, but these are not accessible to the patients cited. During the 12 months I have been in practice in the locality four patients suffering from goitre have come under my care with the following histories, symptoms, &c.

CASE 1.—The patient was a woman, aged 35 years, born in Melbourne but resident in Outtrim for the past seven years. Five years ago she first noticed the swelling in the neck which has got progressively larger ever since. She suffers from attacks of a sense of suffocation and also from occasional attacks of dyspnœa. She exhibits slight exophthalmos and throbbing of the carotid arteries and a uniform enlargement of the thyroid gland which is of about the size of a large hen's egg. She is morose, suspicious, and melancholy in disposition and complains of nervousness.

CASE 2.—The patient was a woman, aged 35 years, who was born and spent the early part of her life in Cumberland but came out to Australia in early adult life and has been resident in this district for the past five years. She had a slight goitre in England but it caused her no trouble until about 12 months ago when it began to enlarge rapidly. The enlargement of the gland has been accompanied by paroxysms of dyspnœa and hot flushes. The swelling, which is about as big as a small orange, involves the whole thyroid unequally, the right lateral lobe is by far the larger mass and pushes the trachea wall over to the left. It undergoes remarkable changes in size in the course of a few days. The patient is very nervous and emotional and readily weeps on being questioned.

CASE 3.—The patient was a girl, aged two and a half years, who was born and brought up in the district. The parents state that the child was born with a goitre and their then medical attendant stated the same to them. The thyroid is of about the size of a walnut and uniformly enlarged (the thymus also can just be felt behind the sternum); it is not tender and has only enlarged proportionately to the growth of the child. The child suffers from *petit mal* and sometimes from bronchitis. The parents state "she occasionally complains of feeling choked."

CASE 4.—The patient was a woman, aged 32 years, who was born and spent the early part of her life in Cumberland; she came out to Australia at about 20 years of age and has been resident in the district for the past seven years. She has had a goitre ever since she can remember; it is stationary and gives rise to no symptoms (she consulted me for other troubles) and has got neither larger nor smaller since her stay in the district. The thyroid is uniformly enlarged to the size of a hen's egg.

It will be seen from the above that not only will rain water sometimes fail to benefit cases of existing goitre but two of the above-mentioned cases must have actually developed under the *régime*.

I am, Sirs, yours faithfully,
A. E. TAYLOR, M.B., B.C. Cantab.
Outtrim, South Gippsland, Australia.

CORDITE-EATING.

To the Editors of THE LANCET.

SIRS,—With reference to your note on Cordite-Eating in THE LANCET of Oct. 17th, p. 1137, it would seem that the first reference to cordite-eating by soldiers appeared in the *New Zealand Medical Journal* for March, 1902. In that number it is suggested by Surgeon-Captain Purdy, 6th N.Z M.R., that cordite was eaten by men for the purpose of malingering and that the effect produced was a temporary pyrexia resulting in the individual affected being sent off duty. I should think it probable that many cases of ill-defined and continuous fevers for which no obvious cause could be discovered—cases in which the temperature would rise to over 102° F. at night and drop to normal in the morning—were cases of cordite eating. It is obvious that a man with a "temperature" would be sent off duty and if it continued he would be sent to hospital and kept there till his "fever" left him. The same thing doubtless applies to cases of "disordered action of the heart" and other anomalous ailments prevalent in military practice. When one considers the facility with which, even in the general hospitals, cordite could be obtained and what the soldiers on active service had to put up with, one considers why such a convenient form of malingering by those addicted to such practices was not resorted to more.

I am, Sirs, yours faithfully,
J. S. WARRACK, M.D. Aberd., D.P.H. Cantab.
Gravesend, Oct. 27th, 1903.

A SIMPLE METHOD OF PERFORMING INTESTINAL UNION

To the Editors of THE LANCET

SIRS,—As I have received numerous inquiries regarding the intestinal bobbins described in THE LANCET of Oct 24th, p 1156 may I say that these are to be procured from the Medical Supply Association 56 Sauchiehall street, Glasgow I shall esteem it a favour if you can give this publicity

I am, Sirs, yours faithfully,

Glasgow Oct 31st 1903 ALEX MACLENNAN

THE USE OF GLYCERINE INSIDE THE UTERUS

To the Editors of THE LANCET.

SIRS —I thank you for your criticism of my paper on the intra uterine use of glycerine and formalin for drying the uterus after irrigation I quite acknowledge the danger of injecting glycerine into the pregnant uterus to induce labour, but in that case the glycerine is injected between the membranes and the uterine wall and there is the danger of it separating the placenta and being forced directly into the maternal blood stream This I believe, is what actually happened in those cases in which untoward symptoms followed its use When, however, the uterine sinuses are closed by contraction of the uterus after delivery and the formation of blood clot this risk is not present Again, the glycerine in my method is injected through a catheter with a return flow and any remaining is expressed

Into the merits of the question of uterine irrigation I will not ask you to let me enter, though personally I am now impressed with its usefulness The point to which I wished to draw attention was the harmful effect of the water left in the uterus—a condition which is obviated by the passage of glycerine through its cavity after completion of the irrigation Further experience of this method since writing the paper has confirmed my belief in its efficacy

I am, Sirs, yours faithfully,

Glasgow Nov 2nd 1903 DAVID WATSON

RELAPSES IN SCARLET FEVER

To the Editors of THE LANCET

SIRS —Dr C DIXSON, in THE LANCET of Oct 24th p 1193 mentions his experience of relapses in scarlet fever and asks if others have had similar experiences

In the year 1892, when I was medical officer to the Nottingham Borough Isolation Hospital, I collected notes of 600 consecutive cases of scarlet fever attended by myself on the basis of which I wrote a paper on the complications of scarlet fever, from which I take the following extract "Second attacks or relapses should, perhaps, hardly come under the head of complications, but as they are hardly mentioned in the ordinary text books, or passed over as being very rare, I may state that there were 10 cases on my list (1 6 per cent of the total number) in which a fresh rash with rise of temperature and the development of other typical symptoms occurred when there was no doubt that the patient had originally had scarlet fever This occurred in the second week in two cases, in the third week in four, in the fourth week in two once in the sixth, and once in the seventh week of the original attack ' With regard to the explanation of such cases I do not see any difficulty in accepting the theory that in a minority of individuals the acquired immunity conferred by an attack of scarlet fever is of a more or less evanescent character and that when such persons are brought into or kept in, an atmosphere highly charged with the micro organisms of the disease they will catch the infection more than once, a relapse only differing from a second attack at a later period by the shortness of interval between its occurrence and that of the original disease

I leave it to others to dogmatise as to the exact nature of the antitoxins or other ferments which are concerned in the process and will only, in conclusion, mention my own case as an instance of what I mean As a child of 13 years I contracted scarlet fever and distinctly remember the annoyance of having to go back to bed again with a fresh rash and rise of temperature which came on during my convalescence As others of my family had the disease at the same time there was plenty of opportunity for re infection Many years later, during my term of office at the Nottingham Isolation Hospital, at a time when I had to deal with a considerable number of severe cases of scarlet fever and was frequently occupied in brushing ulcerated throats with antiseptic solutions, I exposed myself to an atmosphere highly charged with the poison and was in consequence again attacked by the disease, attended by very severe throat symptoms Trusting you will excuse the length and the personal nature of this communication,

I am, Sirs, yours faithfully,

Nov 4th 1903 *J DARLEY WYNNE M B Dub , D P H , &c*

THE CENTRAL BRITISH RED CROSS COMMITTEE

To the Editors of THE LANCET

SIRS,—Permit me to draw the attention of your readers to the following

The Central British Red Cross Committee has been charged with the duty of making known to the British public the existence of a fund instituted by H I M the Dowager Empress Marie Féodorovna of Russia for encouraging inventors and others to devise improvements in the means of dealing with wounded and sick in the field The announcement of the foundation of this fund was made at the Seventh International Conference of Red Cross Societies held at St Petersburg in May, 1902 The money set apart for the above object, and which is called the Empress Marie Féodorovna International Red Cross Fund, consists of a sum of 100 000 roubles (about £11 000) graciously presented by Her Majesty, the interest of which is to be expended every fifth year in prizes to be awarded at each successive International Red Cross Conference The prizes at the first competition, which will take place in 1907 (country to be hereafter named), will be three in number They will be awarded to competitors who submit, in whole or in part, the best solution of problems connected with rendering aid to the wounded, whether on land or sea, and in the following directions the surest and quickest means of searching for and removing the wounded from the field of battle, the best type stretchers or vehicles for moving the wounded to the dressing stations with the greatest rapidity and with the least degree of suffering , the means of saving lives at sea , the best installations in moveable hospitals, wagons, ships, &c , for the final evacuation of wounded and sick The competition is an open one and intending competitors are informed that they will have to send their inventions to the exhibition of ambulance material which it is proposed shall be held quinquennially in connexion with the International Conference of Red Cross Societies Further details can be obtained on application to the honorary secretary Central British Red Cross Committee, 68, Victoria street, London S W

I am, Sirs, your obedient servant,

KNUTSFORD,
Chairman

October, 1903

ERRATUM —In the letter published in THE LANCET of Oct 31st, p 1257 headed "The Universities' Mission to Central Africa and signed Oswald A Browne M D Lond ," Dr Browne s degree should have been given as *M D Cantab*

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Plague Epidemic Inoculation for the Punjab – The Decimation of Mhow —The Plague Mortality

AN attempt is to be made to revive the practice of inoculation in the Punjab which was so grievously upset by the unfortunate accident at Mulkowal about this time last year "Government has done all in its power to bring the advantages of inoculation prominently to the notice of the people ' and "all that can be done now is to afford the greatest possible facilities for the inoculation of such persons as may desire of themselves to be inoculated.' These are the latest announcements but no information is given of the confidential report of the "accident committee." Perhaps we shall never know how the misfortune arose which broke down the Punjab Government's grand scheme of universal inoculation. The inference from the silence is that the finding must be an unpleasant one. There are three possible explanations—viz., that it was an accident in manufacture or an accidental contamination subsequently, or that it was an intentional crime and that the committee has not been able to discover the cause.

To revive inoculation all officers of the medical department with qualifications of a licentiate upwards will be allowed to perform it and will be furnished with the appliances, but the inoculators will be stationary not itinerant. Effort is also to be made to induce the people to evacuate infected places, especially in the early stages of an outbreak.

Later news from Mhow reveals the terribly virulent form of plague which has during the monsoon months attacked this city. Half of the population are reported to have left the city which according to the census contained about 35,000 people. On Sept. 4th the death-roll was 140 and for the week ending Sept. 12th 669 deaths were recorded. Up to Sept. 26th there had been 4313 deaths, practically in three months This is probably the worst outbreak that has been experienced, as an eighth part of the population have succumbed and the rate of mortality of the worst week would, if it had continued, have wiped out the whole population in less than a twelvemonth.

The plague mortality throughout India last week was as follows: Bombay Presidency, 9163 deaths; Bombay city, 91; Bengal, 46; Calcutta, 27; Madras Presidency, 127; Punjab, 211; Berar, 794; Central India, 1899; Central Provinces, 404; United Provinces, 80; Hyderabad State, 940; Mysore State, 673; and Kashmir, 7. The disease is increasing in Bombay city but slumbers in Calcutta. A recrudescence is evident in Mysore city and the Government has decided to spend about £20,000 in sweeping away some of the congested slums and in creating open spaces.

Oct. 9th.

LONDON TEMPERANCE HOSPITAL.—A large company assembled at the London Temperance Hospital, Hampstead-road, N.W., on Oct. 28th, when the Right Hon. the Lord Mayor and the Sheriffs of the City of London attended to inaugurate the scheme for rebuilding the out-patients' department. Alderman Sir T. Vezey Strong, in presenting an address of welcome to the Lord Mayor, said that the hospital had been in existence over 30 years and had so grown that it had become absolutely essential that the present building should be enlarged. While the distinctive principle of the institution was the treatment of disease without the use of alcohol, the medical officers had full liberty of action, the only stipulation being that when alcohol was prescribed the fact should be notified in a book kept for the purpose and its effect upon the patient set forth. During the existence of the hospital something like 300,000 in-patients suffering from every conceivable malady had passed through the wards and had been successfully treated, the rate of mortality comparing favourably with that of any of the general hospitals, and yet it had only been found necessary to prescribe alcohol in something less than 2 per 1000 of the cases treated. The new building scheme would entail an expenditure of about £10,000 and they appealed to the public to help them to carry on this beneficent work. The Lord Mayor, in replying, said that the London Temperance Hospital had amply justified its existence. The statistics which the chairman had given showed conclusively that alcohol was by no means a necessity in medical treatment and if they could treat disease without that fell enemy of the human race, which they as magistrates knew only too well was the cause of a great deal of the crime which prevailed in this nation, then they were doing indeed a most excellent and noble work. He was surprised that they confined themselves to a paltry £10,000 and certainly that sum should be readily forthcoming. He congratulated them on having secured the approval of King Edward's Hospital Fund which meant that the managers of that fund, after having gone carefully into the matter, were satisfied that the hospital was worthy of support. Dr. Dawson Burns, Sir W. J. Collins, and the Archdeacon of Westminster also spoke and the proceedings then terminated.

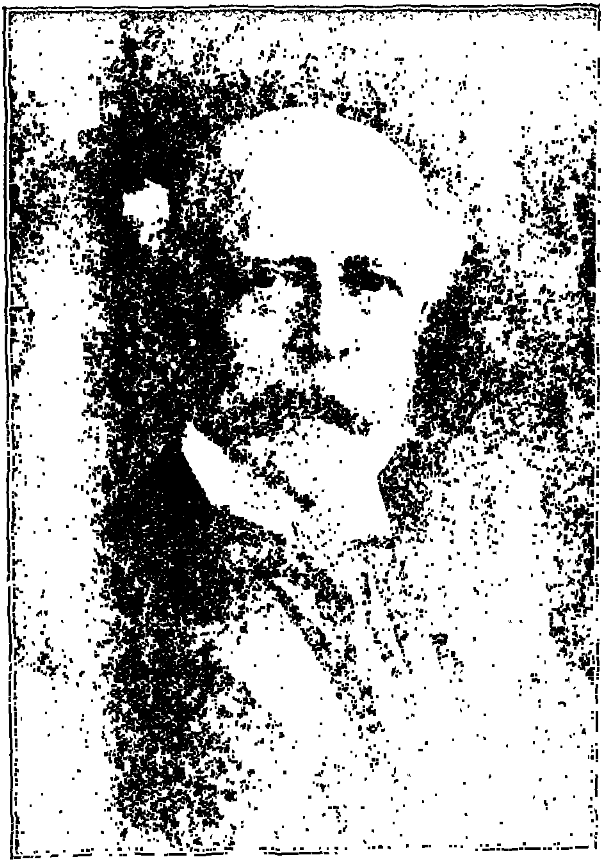
Obituary.

SIR GEORGE FREDERICK DUFFEY, M.D. DUB., F.R.C.P. IREL.

SIR GEORGE FREDERICK DUFFEY, ex-President of the Royal College of Physicians of Ireland, died after a long illness at his residence in Fitzwilliam-place, Dublin, on Oct. 13th. He was a graduate in Arts and in Medicine of the University of Dublin, in the medical school of which he had as an undergraduate obtained the medical scholarship of his year. Taking the degree of M.B. in 1864, he entered the Army Medical Service in 1867 as assistant-surgeon in the 24th Regiment and after nine years' service resigned his commission to settle in Dublin. In 1871 he proceeded to the degree of M.D. In 1876 he was appointed physician to Mercer's Hospital, which position he filled until 1882, when he was elected physician to the Royal City of Dublin Hospital and lecturer on materia medica to the Carmichael College of Medicine and Surgery. After the amalgamation of that College with the Ledwich School of Medicine and the School of Surgery of the Royal College of Surgeons in Ireland he was appointed professor of materia medica and pharmacy to the combined schools. In 1873 he became Fellow of the Royal College of Physicians and in 1896 was appointed its President. In the summer of 1897 he was still occupying the presidential chair and when in this year various honours were bestowed in connexion with the celebration of the diamond jubilee of Her late Majesty Queen Victoria Dr. Duffey received the honour of knighthood. During his brilliant and industrious career he filled many offices and appointments. He was examiner in materia medica in the Queen's University before its dissolution, extern examiner in the Institute of Medicine in the University of Dublin, inspector of examinations for the General Medical Council, and visitor for His Majesty's Privy Council in Ireland. Sir George Duffey had literary tastes and contributed many papers to the medical journals, the first being a valuable account of Mediterranean fever as observed by himself during his residence at Malta. He founded and managed the *Irish Hospitals Gazette*, a small journal which ultimately became merged in the *Dublin Journal of Medical Science*. He was also editor and part author of "Griffith's Materia Medica and Pharmacy" and author of "Suggestions for a Plan of Taking Notes of Medical Cases," a work which reached a second edition in 1890. In 1871 he married Agnes, daughter of the late John Cameron of Dublin and sister of Sir Charles Cameron, Bart., who represented Glasgow in Parliament for many years. His family consisted of two sons and three daughters. Some years ago his elder son, Lieutenant George Duffey, died from yellow fever while serving with his regiment in the West Indies. His younger son, Dr. Arthur Cameron Duffey, is a lieutenant in the Royal Army Medical Corps and in 1899 acted as special commissioner to the United States on behalf of the Cancer Research Society. Sir George Duffey was an exceedingly popular and useful member of the medical profession in Dublin and a most regular and diligent supporter of many scientific societies. At the last meeting of the governors of the Royal City of Dublin Hospital he was appointed consulting physician to that institution, while a motion was passed expressing the regret of the governors and members of the staff on account of his enforced retirement from the duties of visiting physician. His death at the comparatively early age of 60 years has left a gap in the ranks of his profession which will not soon be filled. The attendance at the funeral, which took place on Oct. 16th, was, as might have been expected, very large and representative.

At the annual general meeting of the Royal Academy of Medicine in Ireland the following motion was passed:—

> That the Fellows of the Royal Academy of Medicine in Ireland assembled at this annual general meeting wish to record their regret and sorrow at the death of Sir [illegible] original Fellow of the Academy and one of the trus[illegible] was one of the most steadfast and faithfu[illegible] Year after year he submitted to one or [illegible]ications of great scientific, clinical, or pathological interest and value and on all occasions he shed lustre upon the Fellowship of the Academy by the high standard of professional honour which he set before him and up to which he consistently lived. The Fellows of the Academy also desire to convey to Lady Duffey, Dr. Arthur Cameron Duffey, and the other members of the family of their friend and colleague an expression of sympathy with them in their bereavement and sorrow.



SIR GEORGE FREDERICK DUFFEY, M.D., DUBLIN.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University and Vivisection.

MASON COLLEGE never possessed a licence for purposes of vivisection. The late Mr. Lawson Tait, who though himself a vivisector in his earlier days, as the recently published letters of Charles Darwin have shown, afterwards postured as one of its opponents and was for a number of years one of the trustees of the College and there were in the city other active opponents of scientific research of sufficient influence to make it inadvisable for the College in its youthful days to court the agitation which it was thought would have been directed against it had any steps in the direction indicated been taken. There has, however, for long been a feeling on the part of all connected with the institution that the time had come when the reproach should be taken away from the College and when it became a university it was obvious that no long postponement of this event could take place. As a matter of fact, the University applied for, and obtained, a licence during this summer, a fact which it would seem has only just come, and incorrectly come, to the ears of the anti-vivisectionists, since they have commenced an agitation the object of which is to "protest against a licence being granted to the authorities of the Birmingham University of a laboratory for vivisectional purposes." The papers have been flooded with the usual style of letters in which abusiveness and ignorance are equally noticeable. A striking contrast to most of these effusions has been a letter from a local practitioner, *Dr. F. J. V. Hall*, who says that when himself a student he witnessed vivisections but never anything which could be described as cruelty and adds in reply to a letter from the chairman of the National Canine Defence League, "If any one of the statements he has made—and professedly from knowledge—were true, I would back the students to lynch the operator before he had time to torture the animal." Needless to say, this direct testimony has made no impression on the anti-vivisectionists but the most encouraging sign of the times in connexion with the present agitation is the fact that it has not succeeded in securing the support of a single person of any local importance. At the meeting held on Oct. 27th to protest against the giving of the licence there was not one person on the platform of any influence in the city and the principal speakers were the well-known Mr. Somerville Wood and Dr. George H. Brand, a practitioner in Northampton. The meeting was the most eloquent testimony to the fact that the common sense of Birmingham is ranged on the side of the University. Beyond this fact the most interesting point in connexion with the meeting was the reading of a letter from the Right Hon. Joseph Chamberlain, Chancellor of the University, addressed to the secretary of the Anti-vivisection Society in Birmingham:—

> MADAM,—I beg to acknowledge the receipt of your letter of the 19th inst. and to say that I am most certainly opposed to the torture of animals, but that I entirely approve of the application of the [illegible] to promote [illegible] Sir Oliver [illegible] ssibility of [illegible] tter to the [illegible]
>
> I am, Madam, yours obediently,
> J. CHAMBERLAIN.

On Oct. 31st an account was published in one of the papers of an interview which the reporter had had with the Dean of the Medical Faculty of the University in which the reasons for obtaining a licence and the limitations placed thereon were set forth. It is to be hoped that this will settle any doubts which may have arisen in the minds of any well-meaning though ill-informed persons, though it is too much to expect that any effect will be produced by it on the anti-vivisectionist party.

The Medical Mission.

The annual meeting of this society has recently been held in the new mission hall in Floodgate-street, the Lord Mayor being in the chair. His lordship after expressing the interest which he had taken in the society since he settled in Birmingham said that the record of 120,473 cases dealt with, involving over half a million of attendances, was one of which any mission might well be proud. He drew attention to the fact that the annual subscription list was only £500 and that there was a deficiency amounting to £271 which he hoped would soon be wiped off and its recurrence rendered impossible by larger assistance being forthcoming. Mr. H. Bagster Wilson, the medical superintendent, reported on the work accomplished by the mission not only on the medical but also on the religious and social side. The religious services were appreciated and much success attended the mothers' meetings, the sewing class, the Saturday afternoon and evening socials, the youths' meetings, and the various Sunday gatherings.

Orthopædic and Spinal Hospital.

The eighty-sixth annual meeting of this charity has recently been held, also under the presidency of the Lord Mayor. During the past year there was a diminution in the number of in-patients owing to the fact that the wards had to be closed for some time on account of an outbreak of scarlet fever. After thorough disinfection under the supervision of the health committee these have again been opened and are in full work. A deficiency of nearly £700 on the year's working was reported. The Lord Mayor suggested that as the instrument account amounted to something over £700 this particular part of the work should be made a separate fund, as he was sure that a number of their subscribers would gladly contribute additional sums for that special object.

Staffordshire Police and Attempted Suicides.

A singular order recently issued by the chief constable of Staffordshire to the police under his control seems likely to cause considerable difficulty in connexion with cases of attempted suicide brought under the notice of the police in Handsworth, a suburb of the city, with which it is absolutely continuous, though technically outside its boundary and actually in Staffordshire. This circular is as follows: "Any person attempting to commit suicide must not be taken to the General Hospital by the police, as the hospital authorities decline to receive cases brought by the police unless arrangements are made for watching them. If the relatives or friends are prepared to pay the hospital authorities for watching the patient there need be no difficulty, but friends who undertake to pay must accompany the patient to the hospital to make the necessary arrangements, as the police cannot undertake any responsibility in the matter, the patient not being a prisoner. In other cases where no one is prepared to pay for watching the relieving officer must be communicated with, and the patient must be taken to the workhouse unless arrangements can be made for medical attendance and watching in the patient's own house." The Birmingham police have an invariable practice and that is that the officer who takes a would-be suicide to the hospital remains with him until he is relieved by another constable. As the Staffordshire police have refused to conform to this custom, the authorities of the hospital have been involved in considerable expense in connexion with this class of case, since they have been obliged to engage two attendants for each patient, one for the day and one for the night. They do not think, in justice to their subscribers and to the public, that they ought to be called upon to defray these charges and, as Mr. Howard Collins, the house governor, points out, the hospital authorities are not prepared to make arrangements with the friends or relatives of such patients for the payment of watchers, since, being a charity, the hospital never accepts any payment either from a patient or from his friends. The hospital committee has therefore had no alternative but to refuse such cases when brought by members of the Staffordshire police unless and until they agree to conform to the practice of the Birmingham police. In any case, it seems as if this order would be likely to lead to a very serious loss of time in connexion with the treatment of such cases, for if the patient has to be removed to the workhouse it must be remembered that the relieving officer has a very large district and it might well happen that a considerable time would elapse before he could be found and the necessary order for removal obtained.

Hospital Saturday Fund.

Those responsible for the collection of this fund have not had the satisfaction of congratulating themselves upon raising the £20,000 which has long been the goal of their ambition, though they have made considerable strides in that direction; but in spite of this fact they have handed over their usual contribution of £10,000 to the medical charities of the city, the sum being divided in precisely the same manner as last year.

Guild of St. Luke.

A branch of this guild has recently been formed for the city and district and Dr. Milner M. Moore of Coventry has been appointed Master. It is intended apparently to include dentists amongst its membership, since the first honorary secretary belongs to that profession. The first annual meeting has recently been held at Queen's College but so far as the newspaper reports show does not appear to have been attended by many members of the medical profession.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Salicylic Acid in Jam.

AN interesting case was heard on Oct. 19th at the Knutsford quarter sessions when a Stockport grocer appealed against a conviction for selling a pound pot of jam which was not of the nature, substance, and quality demanded. It was shown by Mr. William Thompson, public analyst of the borough of Stockport, that the pot of gooseberry and raspberry jam contained 2·6 grains of salicylic acid to the pound. It contained 7·7 per cent. of cane sugar, 52·4 per cent. of invert sugar, 3·6 per cent. of other sugars, 32·9 per cent. of water, and 3·4 per cent. of insoluble matter from fruit. He analysed another sample of jam which contained no salicylic acid and it showed 73·1 grains of sugar against 23·3 grains of water, while the sample with salicylic acid contained 63·7 grains of sugar and 32·9 grains of water. The addition of the acid therefore enabled the jam to take up about 9 per cent. additional water. Mr. Thompson said that salicylic acid was not necessary for the making or preservation of jam. Professor S. Delépine agreed with this statement and said that if there were too much water in jam something else than sugar was required to counteract it. "Salicylic acid was a powerful poison and the continuous taking of minute doses would be injurious to children and weak persons." Several representatives of jam-making firms gave evidence that they had used salicylic acid for various periods up to 25 years. Other makers gave similar evidence but admitted that since the Parliamentary inquiry they had reduced the quantity of the acid to two grains, or 0·16 grain per pound. Mr. Herbert Davies, analytical chemist, Liverpool, Dr. Thomas R. Bradshaw, and Dr. E. Rayner of Stockport considered that such a small quantity as that mentioned would not be deleterious but rather an advantage. Sir Horatio Lloyd, in giving judgment, said that the article supplied did not comply with the terms of the statute. And as to its being to the prejudice of the purchaser, they were more or less influenced by the fact that in working-class districts it was the staple food of the children and even in small doses frequently repeated they could not but feel that this would be injurious to them. The decision of the magistrates was confirmed with costs. The defendant's counsel applied for a case to be stated.

Life-Saving at Manchester Baths.

Manchester is not the place where one would expect much interest to be taken in swimming but a good deal is done to encourage the art at the public baths. On Oct. 27th an interesting series of examinations by the Life-Saving Society took place at the Cheetham baths. There was a medical examination in the theory of circulation, respiration, and resuscitation taken charge of by Dr. Ashworth. The land drills in rescue and release included the Silvester, Howard, and Marshall Hall methods of resuscitation. "The water drills were release and rescue four methods, the drowning subject to be carried 20 yards by each method, 100 yards breast stroke, 50 yards back stroke, and object diving." Out of 33 candidates 32 were successful. The classes for instruction are free to all citizens over 16 years of age. This is a municipal enterprise highly to be commended. How far it is taken up elsewhere I do not know, but as it is said that the deaths from drowning round our coasts and in the fresh waters of the United Kingdom alone every year are between 6000 and 7000 it is very desirable that the art of swimming and the technique of life-saving should be more widely known and practised. The difficulty and danger involved in the attempt of a mere swimmer to save the life of a drowning person are well known and if, as it is stated, a swimmer can in the course of ten or 12 lessons become so proficient as to give valuable aid in saving life without risk or danger to himself this part of the work of the baths committee may be cordially approved.

St. Mary's Hospital.

The building of the new hospital for women in Oxford-street is practically complete and it is expected to be ready for patients about the end of the year. £25,000, however, are required to defray the cost and one of the last acts of Bishop Moorhouse while he was still Bishop of Manchester was to preside at the annual meeting on Oct. 28th and to make an eloquent appeal for increased support. The medical charities of Manchester are largely made use of by those living in a wide area from which few subscriptions are received and the severe words of the bishop are quite justifiable. "It seems to me, I must confess," he said, "an anomalous, and I will even say a scandalous, state of things that no fewer than 100 great towns in the vicinity of Manchester are receiving valuable assistance from this institution and return no annual subscriptions." The burning words with which his appeal was enforced ought surely to rouse the slumbering philanthropy of "the 100 great towns in the vicinity of Manchester."

The Salford Royal Hospital.

The annual meeting of the friends of the Salford Hospital was held on Oct. 29th, under the presidency of the Mayor, Alderman Stephens. As is so often the case, the report told of increased work, greater calls on the institution, and a deficiency for the year of nearly £2000. The annual subscriptions only amount to £1000 which the chairman of the board considered was not creditable for a population of from 220,000 to 230,000. Dr. J. Dixon Mann read the medical report which stated that "the record number of patients treated during the past year afforded additional evidence of the need for enlarging the hospital." This seems the universal cry—more calls on the charity, absolute need for extension, insufficient subscriptions, in debt, but must enlarge, and so on. How long can it go on? Is it absolutely necessary? There is a large section of the population of our towns obtaining the help of hospitals and looking to it as a right, who might, and ought to, pay something for the treatment and care they obtain but for whom "self-help" has no charms. The whole question of hospital management and the equitable treatment of the private practitioner requires consideration.

Victoria University and the General Medical Council.

The annual meeting of convocation of the Victoria University of Manchester was held on Oct. 28th at the Owens College. Dr. P. McDougall proposed a motion in favour of the election of the representative of the University on the General Medical Council by the medical graduates who are also members of convocation. This was seconded by Dr. John Brown, and supported by Dr. Sinclair who made, as reported, a characteristic speech. He is stated to have said that the General Medical Council was unfit for the duties which it had to perform; that the Direct Representatives on the Council were like Labour Members in Parliament, they represented the lowest interests from the narrowest point of view; and that the medical practitioners throughout the country had no common interests except their own. "The ordinary medical practitioner was not an educated man and liked to talk about the learned professions, whilst as a rule he could not spell. Graduates of a university would have some common object." One could almost imagine that Dr. Sinclair may have been unfortunate as to his associates. After some further discussion an amended motion was passed:—

> That in the opinion of convocation it is desirable that the representative of the Victoria University of Manchester upon the General Medical Council should be nominated for election by convocation by the medical graduates who are also members of convocation.

Poor-Law Cottage Homes.

The cottages homes at Styal were built by the Chorlton board of guardians about five years ago at a cost of £60,000 and with a receiving home provided accommodation for 308 children. On Oct. 28th the Bishop of Chester opened an important extension. There are four blocks of buildings and eight semi-detached homes to accommodate 15 children each, a total of 120. The cost of the new portion, including furnishing &c., is £15,332. In the course of an interesting address the bishop spoke in commendation of the course adopted in bringing the children out into the country districts.

Cheshire Farmers and Anthrax.

Two farmers were summoned at the Eddisbury petty sessions on Oct. 26th for the non-notification of anthrax. A bull belonging to one of them was taken ill and a veterinary surgeon said that the animal was suffering from acute pneumonia. The defendant, instead of sending for medicine, "stuck the bull and an assistant was afterwards found to be suffering from anthrax" He was taken to the Chester Infirmary and recovered The carcass was sold and eight days after it was found that some of the purchasers' pigs were suffering from anthrax, whereupon the veterinary surgeon gave a certificate that the bull had suffered from the same disease The magistrates decided not to convict but the chairman said that although the defendant might have been ignorant of the existence of anthrax he should l the animal to remain under the care of the rgeon until its real condition was discovered inst the other defendant was withdrawn The serious that it may be thought the defendants asily However, the magistrates requested that d do their utmost in helping the authorities to spread of the disease, a result which does not ble

How Small pox is Spread

been about 30 cases of small pox at Glossop ceable to one house A young man who worked ridge went home to Glossop ill with small pox nitary inspector made inquiries at the house the at his wife and daughter had gone to Sheffield, y were ill upstairs with the disease, evidently the son The magistrates pointed out that the l cost the corporation £300 and caused two defendant was fined £4 14s

ND WESTERN COUNTIES NOTES

ROM OUR OWN CORRESPONDENTS)

Herefordshire Medical Association

THE annual meeting of the Herefordshire Medical Association was held at Hereford on Oct 28th under the presidency of Dr J B Fitzsimons Dr H B Pope of Kington was elected President for the ensuing year An interesting account was given by Dr Paul M Chapman of an outbreak of cerebro spinal meningitis among the occupants of a large school The history of the association since its establishment in 1858 was narrated by the honorary secretary, Mr Edgar F Morris, who brought into prominence the activity displayed by the original members in the suppression of unqualified practice in the county

University College of North Wales

The half yearly meeting of the governors of the University College of North Wales was held on Oct 28th under the presidency of Lord Kenyon It was reported that there was an increase in the number of students as compared with last year The chairman stated that in all probability £5000 would be received from the trustees of the late Dr Evan Thomas and the council had decided to allot that sum to the new building fund and to name the portion of the college which was thus built after the benefactor

University College of South Wales

The Cardiff town council has accepted the invitation of the University of Wales to attend in state the annual congregation on Nov 14th and the laying of the foundation stone of the new buildings in Cathays park

University College, Bristol

The annual distribution of prizes in connexion with the faculty of medicine of University College, Bristol, took place on Oct. 30th, when Sir William Ramsay made the presentations to the successful students Mr P J Worsley, who presided, in welcoming Sir William Ramsay said that they knew him better as Principal Ramsay who had come to University College Bristol *22 years ago and had helped to* establish for it the high position which the college had taken in scientific teaching After the distribution Sir William Ramsay delivered an interesting address on the professional training of a medical student and in the evening he was the principal guest at the annual dinner of the Bristol Medical School

SCOTLAND

(FROM OUR OWN CORRESPONDENT.)

General Council of the University of Edinburgh

THE statutory half yearly meeting of this body was held in Edinburgh on Oct 30th The chair was occupied for the greater part of the meeting by Principal Sir William Turner. The matter of greatest interest which came before the council was the report of the business committee of the council on the draft ordinance dealing with the institution of degrees in veterinary medicine and surgery and regulations relative thereto The ordinance says that "it is expedient that the University of Edinburgh in order to improve and encourage higher veterinary education, should institute degrees in veterinary medicine and surgery and frame regulations for the same" In accordance with this view the University Court proceeds to institute the two degrees of Bachelor and of Doctor of veterinary medicine and surgery The regulations for the examinations for these degrees are to be prescribed by the Senatus with the approval of the University Court and are to be *administered* by a committee which is to be composed of professors or lecturers in the University and of others conversant with the subjects of veterinary education The ordinance then deals with the examinations, and first, as regards the preliminary examination, the subjects are English, Latin, elementary mathematics, and Greek, or French or German, and the extent of this examination is to be determined by the Senatus Passing to professional education it is enacted that the course shall consist of not less than four academic years and the classes which must be taken are enumerated and these classes, as to range duration, and number of meetings, are also determined by the Senatus with the approval of the University Court It is then enacted that attendance at the Royal Dick Veterinary College, Edinburgh, shall qualify *pro tanto*, for admission to the University *examinations for degrees*, but the University Court shall, after consultation with the Senatus, have power to determine if attendance at other veterinary colleges shall be recognised The University Court shall have power to determine the courses of instruction to be taken in the University and in the Royal Dick Veterinary College respectively, or in any other veterinary college The matter of fees is then regulated and students who are studying with a view to graduation must enrol themselves at the University and pay the ordinary matriculation fee Passing then to the professional examinations for the Bachelor's degree, it is to consist of four divisions The first embraces chemistry, elementary physics elementary botany, elementary zoology, and the anatomy of the bones and joints of domesticated animals, the second division embraces advanced anatomy, histology, physiology, stable management, shoeing, and manipulation of domesticated animals, the third division includes morbid anatomy, pathology, bacteriology, materia medica pharmacy, pharmacology, the [illegible] ary hygiene, and dietetics, anc [illegible] the principles and practice of [illegible] and obstetrics, heredity and general principles *of breeding, and meat inspection* Having passed these in the order specified by the ordinance the candidate before going on to graduation has to show that he has obtaine [illegible] Register of V [illegible] is five guine [illegible] be 25 years of age or upwards and have been engaged for at least three years in the further study or exercise of his profession, he must present a thesis or a published memoir or work, he shall also be examined practically in veterinary medicine and surgery and, in addition, in veterinary hygiene or pathology, or bacteriology, the fee is 15 guineas This ordinance did not meet with the approval of the business committee of the General Council and in its name it was proposed to send back the ordinance to the University Court The proposal was, *however, defeated by a considerable* majority at the meeting held on the above date The business committee has thus been left in a somewhat awkward position

Nov 2nd

IRELAND.

(From our own Correspondents.)

University of Dublin.

THE chair of chemistry recently vacant by the retirement of Dr. J. Emerson Reynolds has just been filled by the appointment of Mr. George Young of Bristol. Dr. E. Percival Wright, who has filled the chair of botany for a long period, is about to retire and there are many candidates for his position. In the School of Physic many important changes in the professorial staff have taken place within a comparatively short period. A note of these may interest readers of THE LANCET who are graduates in medicine of the University of Dublin and such are to be found all over the world. Professor D. J. Cunningham, the distinguished anatomist, has returned to the University of Edinburgh, his *alma mater*, and has been succeeded in Dublin as University professor of anatomy and chirurgery by Dr. Andrew Francis Dixon. Dr. J. M. Purser, for many years King's professor of institutes of medicine, was succeeded after his retirement by Dr. William H. Thompson, formerly professor of physiology in the Queen's College, Belfast. Professor George Fitzgerald, whose lamented death took place last year, although he did not lecture in the School of Physic was nevertheless well known to all medical graduates. He has been succeeded as Erasmus Smith professor of natural philosophy by Professor William E. Thrift, M.A., F.T.C.D.

The Irish University Question.

The principal question at present being discussed in Ireland is the suggested settlement of the difficult problem of Irish university education—a question which many years ago shipwrecked Mr. Gladstone and which the witty Lord Morris advised Mr. A Balfour, when he came to Ireland as Chief Secretary, to leave alone. Rumour says that Mr. Wyndham is most anxious to try his hand at devising a scheme, and there is no doubt that he and Sir A. MacDonnell, his under secretary, are at present making overtures to the various bodies affected and are hearing their opinions on the matter. The scheme adumbrated by the Dublin Castle authorities is to create a great national university for Ireland which will include Trinity College, Dublin, Queen's College, Belfast, and a new fully endowed and equipped Roman Catholic College in Dublin. It is said in the public press that Trinity College was offered a grant of £10 000 a year if it would consent to the plan, the share for Belfast being an additional yearly grant of £15,000, while a sum of £45,000, it is reported, is to be given to the new Roman Catholic College. Each college is to be autonomous and is to have the power of conducting all the examinations for the degrees in the various faculties. The Provost and senior Fellows of Trinity College are opposed to the scheme on the ground that it would be injurious to the interests of higher education in Ireland and to those of Trinity College that there should be incorporated in the University of Dublin a Roman Catholic or other denominational college in which access to the teaching staff and governing body would depend, either in theory or in practice, not merely on literary and scientific attainments, but also on religious denomination. It is said that Trinity College would be most anxious to join with Belfast but not with a college of Roman Catholics ruled by Roman Catholics for Roman Catholics. Then in this scheme what is to become of Cork and Galway and of non-resident students who wish to obtain a degree and who, owing to the Royal University, have vested interests, and what is to be done with female students? There are many people who would gladly see some new scheme, either a modification of the Royal University or even a new plan altogether, if it could be worked out on purely academic lines with the power of conferring degrees on academic grounds alone and with none of the colleges associated in the University either directly or indirectly under ecclesiastical control. The question is a confessedly difficult one and I fear that Mr. Wyndham will no more be able to settle it than was Mr. Gladstone. The whole trend of public opinion is against sectarianism in university life except in Ireland and if Mr. Wyndham attempts a settlement on any basis except academic lines he will probably be defeated. At the meeting of the Senate of the Royal University on Oct. 29th the following motion was passed:—

> That while we are satisfied that the Royal University of Ireland under its present constitution has done good work within the limits of the powers committed to it we are of opinion that the findings of the Royal Commission on University Education in Ireland must, unless followed by some measure of reform giving promise of permanency, react injuriously upon the University and through it upon the most vital educational interests of the country; and therefore we beg most earnestly to represent to the Government the urgent need of taking this question into their immediate consideration.

Poor-law Reform in Ireland.

At a sitting of the Poor-law Commission in Omagh on Oct. 29th Dr. E. C. Thompson, M.P., in giving evidence, said that there were too many workhouses in Ireland; for instance, in county Tyrone, instead of six, as at present, he thought three would do, those of Omagh, Strabane, and Dungannon. He thought the district hospitals should be made really efficient and they, with one efficient surgical hospital manned by a capable surgeon, would form a desirable system. Workhouse hospitals should be taken out of the workhouses altogether and the fever hospitals should be utilised. The hospitals should be removed from the care of guardians who, with the best intention, did not understand what a hospital really should be. There were, in his opinion, no proper nursing and no proper sanitary arrangements in Irish workhouses. They were houses for the poor, where they lingered until they died.

The Ulster Branch of the British Medical Association.

The autumn meeting of the Ulster Branch of the British Medical Association was held in the Guildhall, Londonderry, on Oct. 28th, when the retiring president, Professor T. Sinclair, was in the chair and introduced his successor, Mr. Thomas MacLaughlin, who delivered an interesting inaugural address dealing with the medical history of Londonderry. After the meeting those present—to the number of 70—were entertained by the Derry members of the branch to an excellent luncheon, at which the new president occupied the chair.

Irish Medical Association.

The council of the Irish Medical Association has just issued a circular to the senates and councils of the universities, medical colleges, and schools bringing under their notice the present deplorable condition of the Irish Poor-law medical service with the hope that those entrusted with the provision of medical education may be induced to exert their influence to improve and to reform the service in the interest of many of their present and future graduates and diplomates of medicine and surgery.

Will of the late Mr. Forster Green.

The will of the late Mr. Forster Green, one of the most philanthropic Ulstermen who ever lived, has just been made public. Among many other legacies he leaves £500 to the Samaritan Hospital, Belfast. During his widow's life he directs the surplus income of each year (if any) to be applied in assisting the Forster Green Hospital for Consumption and Chest Diseases and the Epileptic Hospital, Belfast. After her death the trustees are empowered to pay £10,000 to the Forster Green Hospital for Consumption and Chest Diseases for an endowment fund to extend the benefits of its treatment to those unable to contribute in full to their support while under treatment and £10,000 for building and endowing almshouses in Belfast or its vicinity for the respectable poor of Belfast or counties of Antrim and Down, under instructions fully set out in the codicil. Mr. Green died on Oct. 21st.

Nov. 3rd.

PARIS.

(From our own Correspondent.)

French Surgical Congress.

THE annual French Congress of Surgery has just risen and, as usual, it has provided a considerable number of memoirs which can be read hereafter in the "Transactions" and of which abstracts are given in all the journals. The work of the Congress, however, has not, on the whole, been favourably received and there is no occasion to disguise the fact that these annual congresses are gradually declining. As evidence of this, it is sufficient, to remark that there was always abundance of vacant space in the room where the meetings were held, its only occupants being provincial surgeons and some foreign surgeons, whilst the Paris surgeons for the most part were satisfied with entering their names as members and did not absent themselves from their usual occupations for the purpose of taking part in the proceedings. Some animated personal discussions took place

at the general meeting, M Pozzi pressing so vigorously for the alteration of a by law relative to the general secretary that the latter hande
the president of the
active contest from
emerged victorious
year there are to be
two as heretofore It can hardly be expected that this slight modification will be sufficient to restore vitality to a moribund institution

External Perforating Disease of the Stomach

M Hayem has communicated to the Academy of Medicine an account of a lesion of the wall of the stomach which escaped observation until it was recently discovered by him It consists in a loss of substance which occurs not on the internal surface but on the subperitoneal aspect of the stomach and it proceeds from without inwards The lesion passes through three successive phases In the first of these one or more circular depressions are to be seen made as if stamped with a seal their margins being more or less elevated and the bottom more or less irregular or sometimes puckered In the second stage the gastric wall becomes translucent at the place of the lesion, the mucous membrane forms a smooth bridge, and the cellular and muscular layers are greatly reduced in substance In the third stage the lesion forms an ochre coloured hollow on the internal surface, while on the peritoneal aspect it is convex, projecting like a hernia and covered with a perigastric thickening When the ulcer is fully developed there remains only a thin epidermoid layer of the mucous membrane In its first stage the lesion is common enough but it has hitherto escaped description probably because it does not give rise to any symptoms M Hayem's discovery overthrows one of the theories admitted for the explanation of the classic form of ulcer—namely, that it depends on an excess of acidity in the gastric juice tending in some degree to erode the mucous membrane of the viscus Ulcer of the stomach is, in fact met with principally in patients who are the subjects of hyperchlorhydria This explanation however, is inapplicable for an ulcer commencing externally on the peritoneal surface, a phenomenon which can only be accounted for by disorder of tissue nutrition referable to the nervous system just as in the case of perforating ulcer of the sole of the foot which is a result of disease of a branch of the sciatic nerve The external ulcer is in every respect similar to the classic ulcer of the internal coat of the stomach, a feature which supports the opinion of those who see in the latter only the effect of nervous lesions accompanied by malnutrition of certain regions corresponding to the nerve branches in question According to this view hyperacidity of the gastric juice would only act by promoting erosion of the imperfectly nourished tissues

Extraction of a Bullet in Contact with the Left Auricle of the Heart

At the meeting of the Society of Surgery held on Oct 28th M Tuffier showed a non commissioned officer of Spahis aged 24 years who had received a pistol shot in the front of the chest at the attack on Figuig in March 1903 He had been lying almost flat on his horse so that the direction of the bullet was from above downwards Notwithstanding this wound he was able to remain on horseback for half an hour when he was overcome by extreme difficulty of breathing After he was taken to the ambulance station a small wound was found on the left side of the sternum and on the same day he had slight hæmoptysis and fits of dyspnœa. In the course of some days all this passed off and the patient returned to duty Two months later he began to suffer from difficulty of breathing and attacks of dyspnœa, for which he was admitted into the hospital at Mustapha and was then sent to Paris Here he came under the care of M Tuffier who decided on operating after he had for a long time observed the inutility of various kinds of medical treatment for cardiac trouble Radioscopy on several occasions showed the presence of the bullet and its intimate relation to the left auricle, all the movements of which it followed After incision of the integuments and the intercostal space M. Tuffier found, by means of Contremoulin's needle that the bullet was at a depth of five centimetres (two inches) He then resected the second costal cartilage, and the pleural sac being pushed inwards he could with his finger feel the bullet evidently attached to the auricle It was on the surface of the auricle without being encapsuled and nothing further was required to be done in order to extract it, after which the symptoms disappeared

Dwarfs

At the meeting of the Academy of Medicine held on Oct 20th M Poncet presented an interesting memoir on the subject of dwarfs together with a minute description of two examples—a brother and a sister whom he had observed on the banks of the river Ain With respect to the relative proportion of parts their bodily conformation was perfect, unlike that of the individuals who appear in public exhibitions and are in reality the subjects of disease, they may, for instance, be achondroplasiacs—namely, children in whom the development of the bony cartilages has become arrested, frequently in consequence of hereditary syphilis The dwarfs described by M Poncet had however, an irreproachable osseous development, they were small, but the proportions of all the parts were normal M Poncet considered them to be representatives of the pygmies, dwarf races which formerly lived in Europe and
ancients but have long
These pygmies had
followed in history as
late as the tenth century The stature of primitive man was probably small in comparison with the standards of to-day and this condition of dwarfism reappears from time to time by reversion to the type of remote ancestors

Disposal of Tuberculous Sputum

M Barth recommends tuberculous patients to replace the handkerchief or the vessel in which they spit by pieces of paper about four inches square such as might, for instance, be cut from a newspaper A daily newspaper would yield 72 such pieces After spitting in the piece of paper the patient ought to roll it into a ball and throw it into a receptacle kept for this purpose and from time to time emptied into the fire so that the sputa and paper are burned A tin box might be used as the receptacle This method would be practical and inexpensive It would also have the great advantage of doing away with the use of spittoons by phthisical patients for these spittoons encourage the spread of tuberculosis and are a source of danger to the person who has to clean them The small tin boxes suggested by M Barth would cost the Assistance Publique less than porcelain spittoons and they would not be so easily broken

New Hospital Buildings

In November last year the Paris municipal council decided that the Assistance Publique should borrow on its property a sum of 40 000 000 francs (£1 600 000) to be employed in the enlargement and reconstruction of hospitals This loan has been sanctioned by the Chambers and a scheme of the work to be undertaken will shortly be submitted to the municipal council for its approval Several members of the commission which in the council deals with questions relating to the Assistance Publique have already proceeded to Belgium and Holland on a visit of inspection to various hospitals In Antwerp under the guidance of M Ambroise Rendu they will visit the Sturvenberg Hospital of 350 beds, this hospital consists of a series of two storey pavilions arranged round an administrative block They will also visit a new hospital at Liege. Work will not be commenced on the Paris hospitals till next spring A hospital to replace the Pitié will be built on the unoccupied site of the Salpêtrière and when it is completed the Pitié will be pulled down

Nov 3rd

BERLIN

(FROM OUR OWN CORRESPONDENT)

Medical Congresses

NUMEROUS congresses were held throughout Germany during the university vacations especially at the end of September Among the more important of them mention may be made of the meetings of the German Association of Naturalists and Medical Men at Cassel, of the German Practitioners' Association at Cologne or the German Public Health Association at Dresden, and of the Government medical officers at Leipsic

German Association of Naturalists and Medical Men.

At the congress in Cassel the first address was delivered by Professor Ladenburg of Breslau on the Influence of

Natural Science on the Spirit of the Time. The learned professor in his speech, which eventually gave rise to a considerable amount of protest in the daily newspapers, expressed his antagonism to current views on the subject of the inspiration of the Bible, the immortality of the soul, and some other tenets of the Christian and Jewish faiths. In his opinion it would be a decided improvement if sound training in the principles of modern biology took the place of the religious instruction which forms a part of most educational systems. Professor Ziehen of Utrecht delivered an address on the Physiological Psychology of Affections and Sensations; it was, however, of purely theoretical interest. Dr. Alsberg of Cassel spoke on the Effect of Social Influences in bringing about the Degeneration of Certain Races. He said that highly cultured European nations showed obvious racial degeneration. The explanation was that when mankind was living in the state of nature the less resistant individuals perished in accordance with the laws of selection, but in the highly cultured nations the progress of hygiene and medical science contributed to preserve these individuals who in their turn produced descendants still weaker than themselves. The increase of town populations, and especially of factory workers, and the decrease of the rural population—a consequence of the growth of modern industrialism—must also be mentioned, as this class of the community very soon underwent degeneration in consequence of the unwholesome conditions of life in cities. The most terrible foe of humanity was alcoholism. The obvious symptoms of racial degeneration were especially the enormous increase of nervous and mental diseases and the inability of mothers to suckle their infants, the degeneration of the mammary glands being the result of the alcoholism of the progenitors. Professor Rieder of Munich spoke on the use of the Finsen light and the x rays as therapeutical agents. Blue light was said to be serviceable in mania and red light in melancholia. A beneficial action of red light was observed by Professor Finsen in small-pox, an observation in accordance with popular views in some countries, such as Roumania, Japan, and Tonkin where the patients were supplied with red coverlets. Red light also produced good effects in measles, scarlet fever, and erysipelas. Speaking of the Roentgen rays Professor Rieder mentioned different skin diseases, such as favus, ringworm, alopecia areata, and especially lupus, in which the Finsen treatment and the Roentgen rays gave excellent results. In Copenhagen 85 per cent. of the cases of lupus were cured by Professor Finsen, whereas in the Budapest hospital previously to the introduction of the treatment by means of light the proportion of recoveries was 7 per cent. only. In cancer of the skin this method of treatment had also a wide field of action. Lupus ought, he said, to be treated in the sanatoriums for consumptives. Professor Allan Macfadyen of London read a paper on Intracellular Toxins. By exposing bacteria to very low temperatures he was able to examine their intracellular plasma and he found that the intracellular plasma of the bacilli of enteric fever and of staphylococci was highly virulent, as guinea-pigs were killed by injections containing such plasma. Experiments on immunisation were made in monkeys, the result being that the serum of the animal had an immunising action against the bacilli of enteric fever as well as against the intracellular toxin. It has also been ascertained that the opinion that the toxic action of bacteria depended on toxic products of metabolism was erroneous, the toxic agent being in reality present within the intracellular substance of the bacteria themselves. Professor Sir William Ramsay of London read a paper on the Periodic System of the Chemical Elements. Professor Griesbach of Mülhausen read an address on the Hygiene of Schools in Germany. He insisted strongly on the medical supervision of schools by specially appointed medical men. A collective investigation has proved that 80 per cent. of headmasters acknowledged the desirability of medical control. The hygienic defects in the present system were obvious: short-sightedness, for instance, existed in the junior classes in proportions varying from 6 to 31 per cent. in different schools, whilst in the more advanced classes the proportions were from 52 to 83 per cent. From a hygienic point of view it was necessary to have a diminution of the number of school lessons which in Germany occupied from 36 to 40 hours a week and in France from 22 to 26 hours a week. It was also necessary to have a greater number of holidays. In conclusion, he made a reference to the instruction in hygiene given in several towns to schoolmasters and recommended that such instruction should be general throughout Germany. The address of Professor Behring on Tuberculosis has already been recorded in these columns.[1] The congress will meet next year at Breslau. Professor Chiari of Prague and Professor Winkel of Munich were elected presidents of the association.

German Practitioners' Association.

The Practitioners' Association (Deutscher Aerztetag) has held two meetings this year. An extraordinary meeting became necessary in the spring in consequence of the recent amendment of the statutory provisions relative to workmen's insurance and the ordinary autumn meeting took place at Cologne, Professor Loebker of Bochum being in the chair. The proceedings opened with a discussion on the proposed formation of an alliance between the association and the Leipziger Verband, which, as was explained in The Lancet of Feb. 21st, 1903, p. 558, is a combination of medical men having for its object the upholding of the rights of the profession against the high-handed policy of the sick clubs. After a short debate the meeting unanimously sanctioned the proposed scheme of alliance. Another subject discussed by the association was the insurance of the members against sickness and accidents. The matter, after a rather long discussion, was referred to a special committee to be reported on at the next meeting. Owing to the overcrowding of the profession a motion was adopted to the effect that youths leaving school to enter on a university career should be warned against becoming students of medicine. The association finally again discussed the question of club practice and adopted a motion to the effect that the local branches of the association were bound to insist on the free-choice system being introduced in the sick clubs and that the members must abstain from taking any action which might be prejudicial to this result. Members holding appointments as medical officers to clubs with fixed salaries were therefore enjoined to resign their positions as soon as possible.

German Public Health Association.

The first business brought before the meeting of the German Public Health Association was the Prevention of Tuberculosis. Professor Gaffky of Giessen recommended the establishment of public laboratories for the examination of sputa, the compulsory notification of consumption, the isolation of patients in sanatoriums, the disinfection of dwellings free of charge to the householder, and other measures which have already been discussed at length in the different congresses on tuberculosis. Professor Dunbar of Hamburg read a paper on the Regulation of the Milk Trade. He drew attention to the fact that in Germany 150,000 children die every year from diseases caused by unwholesome milk. The control at present exercised by the police was insufficient. He recommended that persons engaged in the milk trade should be required to hold special licences and that these licences should be granted only with the sanction of a commission consisting of agriculturists, medical men, and veterinary surgeons. In the discussion it was argued that these proposals were too stringent and that they would tend to raise the price of milk. Dr. Ohlmüller of Berlin spoke on the Purification of Water by Ozone and Dr. Rumpelt of Dresden discussed questions connected with the Hygiene of Dwellings.

Meeting of Government Medical Officers.

The meeting of the Government medical officers at Leipsic discussed the lunacy laws which are different in the various countries of Germany. There was a general agreement as to the desirability of Imperial legislation to establish uniformity of the lunacy laws throughout the whole Empire. There was, on the other hand, great diversity of opinion with respect to the question of insane criminals, as some of the speakers wished them to be confined in special departments attached to prisons, whilst others held that they ought to be admitted to the general lunatic asylums under special control. Other papers read before the Congress were on the Use of Photography in Forensic Medicine, by Professor Strassmann, and on the Prophylaxis of Contagious Diseases in Schools, by Dr. Tjaden of Bremen.

Nov. 3rd.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, KENNETH, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Banewell District by the Axbridge (Somerset) Board of Guardians.

BROWNE, J. J., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Wigton District of the county of Cumberland.

CHOLMELEY, MOUNTAGU ADYE, L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the "Court One and All," Ancient Order of Foresters, Truro.

FARNECOMBE, W. T., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Selly Oak District of the county of Worcester.

GROGAN, GERTRUDE A., M.B., B.A. R.U.I., has been appointed Second Assistant Medical Officer to the Cambridgeshire County Council Asylum, Wilbourne, Cambridge.

HAMILTON, ARTHUR F., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the West London Hospital.

HESLOP, A. H., M.B., B.S. Durh., has been appointed Second Assistant Medical Officer of the City Asylum, Gosforth, Newcastle-on-Tyne.

LYONS, ALEXANDER, M.R.C.P., L.R.C.S. Edin., has been appointed House Surgeon to the Royal Eye Hospital.

PENBERTHY, W., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Wiveliscombe District of the county of Somerset.

PICKARD, RANSOM, M.S., M.D. Lond., F.R.C.S., L.R.C.P. Lond., D.P.H. Cantab., has been appointed Honorary Surgeon to the West of England Eye Infirmary, Exeter.

TOSSWILL, LOUIS HENRY, B.A., M.B. Cantab., M.R.C.S., has been appointed Honorary Consulting Surgeon to the West of England Eye Infirmary, Exeter.

WILLOUGHBY, W. G., M.D. Lond., D.P.H. Cantab., has been appointed Medical Officer to the Education Authority, Eastbourne.

Vacancies.

For further information regarding each vacancy reference sh made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND U DISEASES, John Bright-street, Birmingham.—Surgical A for six months. Honorarium at rate of 52 guineas per ann

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL, street, Queen's-road, [illegible]

[illegible]

CHARING CROSS HOSPITAL.—Assistant Anæsthetist. Salary £6 Also Medical Registrar. Salary £40 a year, with lunch.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.— to Out-patients.

THE Chief Inspector of Factories, Home Office, S.W., gives n vacancies for Certifying Surgeons under the Factory Act mouth, in the county of Dorset, and at Hinckley, in the of Leicester.

Births, Marriages, and Deaths

BIRTHS.

DOW.—On Oct. 28th, at Lewes, Sussex, the wife of William M.D., of a daughter.

GREY.—On Oct. 30th, at Roseland, Kingsbridge, Devon, the Harry Grey, M.D. Edin., of a son.

SIMPSON.—On Nov. 1st, at Melville street, Edinburgh, the wif G. F. Barbour Simpson, of a daughter.

DEATHS.

LAWTON.—On Oct. 31st, at [illegible] L.R.C.P., M.R.C.S., D.[illegible]

ORMROD.—On the 1st inst., at Hindley, Workington, [illegible] L.R.C.P., M.R.C.S., aged 60 years.

THORNBURN.—On Oct. 30th, at Low Moor, Bothel, John Thornburn, L.R.C.P., L.M., M.R.C.S., Sunnyside, Cocke aged 64 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of B Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A POINT UNDER THE VACCINATION ACTS.

To the Editors of THE LANCET.

SIRS,—Some months ago I vaccinated a child and subsequently inspected the arm and found it "good." The father of the child then [illegible] night who told me that the district medical officer had filled up the paper, so, of course, I do not now expect a visit from the father nor do I expect to get paid voluntarily Now, Sirs, I should like to know if the district medical officer gets the vaccination fee, if the district medical officer is within his right in filling up the certificate. Does this meet with your approval? I may say that the parents have removed from their present address. Thanking you in anticipation,

I am, Sirs, yours faithfully,

Widegate street, E C, Oct 30th, 1903. ISAAC GEORGE.

*** We fear that there may be in this case an attempt on the part of the parent to escape payment and perhaps he has discovered that the services of the public vaccinator were at his disposal gratuitously. We expect that the district medical officer referred to by our correspondent is also a public vaccinator and that such officer has acted under Section 12 of the Vaccination Act of 1871, which provides that "where it appears to the public vaccinator of any district upon personal examination of any child resident in such district who has not been successfully vaccinated by him, that such child has been successfully vaccinated, the public vaccinator may, on the request of the parent of such child, grant a certificate to that effect, and such certificate shall be transmitted and have the same effect as if it were a certificate of successful vaccination by the public vaccinator who gave the certificate." It has, however, to be noted that there is no statutory fee for this certificate and that the public vaccinator must make his own terms with the parent. The public vaccinator is not bound to comply with the request of the parent but it is not desirable except "for very strong reasons" that he should refuse. It appears to us that in the present case, if we rightly interpret our correspondent's letter, the public vaccinator, had he been aware [illegible] 1871, part of which enacts that every "medical practitioner as soon as he has ascertained that the operation has been successfully performed shall deliver to the parent causing the child to be vaccinated a certificate of successful vaccination, in the proper form and duly filled up and signed by him" Our correspondent will do well to think over all the facts of the case in the light of this section before he risks legal proceedings —ED L

THE RÔLE OF SOAP.

To the Editors of THE LANCET

SIRS,—In THE LANCET of Oct 17th, p 1106, I notice under the heading of "The Rôle of Soap" some remarks with regard to a current controversy.

I have read the correspondence in various periodicals and the remarks of some professional men with considerable interest, having made a life-long study of soap from the "chemical" as well as from the "personal" point of view, but I have never seen anyone referring to what has been the universal practice of the company of which I have the honour to be a director in preparing toilet soaps—viz, to finish the soap so that instead of containing any free alkali—either carbonated or hydrated—the soap contains a distinct, though small, proportion of free fatty or oily matter

My theory has always been that it is the free alkali which reduces or abstracts the natural oil of the skin and that a soap absolutely free [illegible] has been studied in any way —I am, Sirs, yours faithfully,

S GODFREY HALL, F C S.

Oct. 21st, 1903. (EDWARD COOK and Co, Limited)

INFORMATION TO THE POLICE

To the Editors of THE LANCET

SIRS,—On finding the body of a baby the police of this district sent an officer to every medical practitioner asking if he had lately attended anyone who might be the mother Should I, then, happening to have a case which I considered one of recent delivery, be right to tell about it?

I am, Sirs, yours faithfully,

Nov. 2nd, 1903. *£10,000 DAMAGES*

*** In the circumstances set out in our correspondent's letter there is nothing to demand, or indeed to justify, his giving information to the police as to any case under his charge which he may consider to be one of recent delivery. The police are bound to make inquiries when they believe crime to have been committed, but no one can be compelled to answer their questions and to make such inquiries of all the medical men in a district in order to get a clue is an unusual and a highly undesirable course for the police to adopt. It would be advisable that all the medical men applied to on such an occasion should answer that they are unable to make any statements to anyone as to matters affecting their patients This is a general rule to which there must occasionally be exceptions arising out of the facts of particular cases.—ED L

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—It is now some few years since I first wrote to THE LANCET on the subject of motor-cars in practice and I venture once again, in response to your invitation, to give the profession the results of my further experience

First, I can cordially endorse the recommendation of the gentleman who advises that two cars should be kept For the last two years I have had two cars in constant use and no horses With the two my expenses for horse hire have been very low and I have always had a car to use; but the occasions on which both were available for a journey might be counted on the fingers, I had almost said on the fingers of one hand.

Next, I once again most emphatically beg of my brother practitioners to have nothing whatever to do with pneumatic tyres. They are the curse of motoring and absolutely and thoroughly unreliable For an ordinary round they are all very well To go to a consultation or an operation in them is to court disaster. Fortunately the current number of the *Autocar* enables me to quote figures in the recent "reliability" trials of six makes of pneumatic tyre:—

One	had a percentage of	46 15	"no trouble" runs
One	" "	0 0	" "
One	" "	53 62	" "
One	" "	23 08	" "
One	" "	100	" "
	(only one car on these tyres).		
One	" "	66 67	" "

I leave it for any of your readers to estimate the desirability of risking this percentage of trouble and hindrance Should any of them wish to study the necessary labour of removing an outer tyre cover and repairing a punctured tube I can refer them to the section on tyre repairs in the Badminton Library book on "Motoring" I can assure them this, that after a most worrying and annoying delay they will be about tired out (no pun intended) and too filthy to visit their next patient, with dirty shirt cuffs and probably some other spoilt clothing. There are some good cars on solid tyres and a considerable number which, in the language of the trade, are "not built to stand solid tyres" To sum up (1) Very few motor cars are worth having at all; and (2) *no car which runs on pneumatic tyres is worth having at all.* Of course, I speak of cars for professional and regular "work." As plaything cars they are another matter. There are some good articles worth study on modern motoring in recent numbers of the *Badminton Magazine.*

I am, Sirs, yours faithfully.

Stratford on Avon, Nov 2nd, 1903. HARRY LUPTON.

To the Editors of THE LANCET.

SIRS,—I am anxious to start a light motor car for my practice and should be glad if any fellow practitioner can help me in the choice of one I live in a very hilly part of Cornwall, a few of the gradients being as steep as 1 in 3 The machine required must therefore be a *first rate hill climber above all things* I should like *one* which would usually carry two persons but having a removeable back seat which could be used if necessary What horse power would be required for the work and how well does a motor car get on with snow on the ground, also can motor-cars be started on a hill without assistance? I shall be very grateful for any suggestions

I am, Sirs, yours faithfully,

Oct. 27th, 1903 TRAMITE RECTA.

CRIPPLED CHILDREN'S CHRISTMAS HAMPERS.

To the Editors of THE LANCET.

[illegible] of your columns to remind [illegible] Christmas hampers to [illegible] metropolis? These welcome [illegible] Guildhall by the Lord Mayor [illegible] when, by permission of the Corporation, we entertain some 1200 ragged school children. His Majesty the King has again given a donation to the fund which it is my privilege to bring to the annual notice of the public. The Right Honourable General Sir Dighton Probyn, keeper of His Majesty's Privy Purse, writes me, Oct 19th. "I am commanded by the King to send you the inclosed cheque for £10 10*s.* as a donation from His Majesty to the Poor Children's Banquet and Cripples' Christmas Hamper Fund which you so kindly organise on their behalf." I am hoping that this year we shall not only be able to say that we have denied no deserving applicant, but that we may have, as we had last year, a little balance in hand to meet those extremely pitiable cases in which a crutch, a cork leg, or the loan of an invalid chair is more welcome even than the hamper. All through the year the work (by the Ragged

School Union) of registration, visitation, and relief continues or we could not undertake the hamper distribution on such a scale with the certainty that not one goes astray or falls into undeserving hands. The little cripple entertains the family and on a modest estimate the fund brightened the lives last Christmas of over 30 000 of the poor of London. I am in receipt of hundreds of most gratefully worded letters. Donations may be sent, as heretofore, to me, addressed Little Cripples' Christmas Hamper Fund, 69, Ludgate-hill, London, E.C. I am, Sirs, yours faithfully,

London, E.C., Oct. 31st, 1903. W. P. TRELOAR, Alderman.

P.S.—This is the tenth year of my fund and every year I have been increasingly successful.

BURGUNDY *v.* CLARET.

To the Editors of THE LANCET.

SIRS,—"A Man of Kent" states that "no wine can equal French burgundy" to produce "the desired effect either of recuperation or of blood making." I assume he has tested the effects of the best South Australian burgundies and I should like to know why he differs from the opinion of other medical men.

I am, Sirs, yours faithfully,
H. ALLFRDALE GRAINGER,
London, Nov. 3rd, 1903. Agent-General for South Australia.

MEDICAL OFFICERS TO SCHOOL BOARDS.

To the Editors of THE LANCET.

SIRS,—I should be obliged for any information from medical officers of school boards respecting their duties and more particularly those concerned with special ophthalmic and aural work.

I am, Sirs, yours faithfully,
JOHN GRIMSHAW, M.D. Lond., &c.
142, Whetstone-lane, Birkenhead, Nov. 3rd, 1903.

THE GENERAL MEDICAL COUNCIL AND MEDICAL MEMBERS OF PARLIAMENT.

IN reference to a report which appeared in the *Evening News* of Nov. 3rd stating on the authority of the *Liverpool Post* that "the Medical Council has resolved to invite medical M.P.'s to confer with the Committee with a view to forming a medical and public health committee in Parliament," we are authorised by the Registrar of the General Council of Medical Education and Registration of the United Kingdom to announce that there is no truth in the statement.

THE BRITISH MEDICAL BENEVOLENT FUND.

THE following sums have been received in response to Sir William Broadbent's appeal:—

	£	*s.*	*d.*		£	*s.*	*d.*
Sir William Broadbent, Bart.	50	0	0	Dr. Mary Thorne	1	1	0
Miss Broadbent	5	0	0	Dr. Hector Robinson ...	1	1	0
Dr. H. De Tatham ...	25	0	0	Mr. E. H. Hicks	2	2	0
Dr. Edward Martin ...	1	1	0	Dr. Moon	5	5	0
Dr. I. Burney Yeo ...	5	0	0	Dr. Barkett	1	1	0
Dr. J. P. Stewart	1	1	0	Dr. R. J. Kerby	10	10	0
Mr Thomas Moreton ...	2	2	0	Dr. M. Greenwood	1	1	0
Dr. Price Williams ...	5	0	0	Dr. W. Andrews	0	10	0
Mr. M. Cutcliffe	1	0	0	Dr. M. J. Doinjo	1	1	0
				Mr. Rayley Owen	1	1	0

Dr. Satchell offers a donation of ten guineas on condition that 16 other donations of £5 each or eight of £10 each are received in response to the appeal before the end of December. The sums received do but little more than cover the amount already granted in relief and leave little to meet the demands outstanding which had to be postponed at the last meeting for want of funds, and make no provision for the applications which have been received since and which will increase in number as the winter approaches. Further help is urgently needed. Subscriptions and donations will be thankfully received by the treasurer, Dr. Samuel West, 15, Wimpole-street, W.

MUSICA LÆTITIÆ COMES, MEDICINA DOLORUM.

THOSE members of the medical profession who can find time to go to concerts—and there is no greater intellectual relaxation than to listen to really good music—will generally find their opportunity at Queen's Hall, Regent's-street, London, W. On Wednesday, Oct. 28th, Mr. Emil Paur conducted at a concert of which the chief items were the C minor symphony of Brahms, and a piano concerto by Mr. Emil Sauer, the part for the solo instrument being played by the composer. On Saturday, Oct. 31st, the first of the Symphony Concerts took place. A very fine performance was secured by Mr. Wood of Brahms's symphony in E minor with its masterly final movement. Other items were the delightful overture to Peter Cornelius's "Barber of Bagdad," an almost unknown work, two tone poems by Arthur Hervey, and the A minor piano concerto of Schumann with Miss Adela Verne in the chief part.

◆

F. E. H.—Mild or anomalous cases of scarlet fever, the nature of which is unrecognised, have usually a large share in the spread of this *disease during an epidemic. On the facts reported we think* that the medical officer of health, in his endeavour to deal thoroughly with the outbreak in the village, was right in desiring to examine the suspected cases. It would have been better if he had been able to make his visits together with the medical practitioner; and we think that an attempt to do this should have been made, though in the country appointments for this purpose are difficult to arrange. In the present instance, where the medical officer of health is not in private practice, we do not think that the medical practitioner need object to the patients having been examined in his absence for the purpose indicated. In the matter of the correct diagnosis the facts are in dispute, and we are unable to give an opinion. In general, we think that the occasions on which a medical officer of health would be justified in expressing to parents any doubt which he entertains as to the correctness of diagnosis in a case of infectious disease must be extremely few.

S. H. S.—A patient has a perfect right to change his or her medical man. It is courteous of the patient to inform the medical man who has been superseded of the change but there is no obligation to do so on the part of the patient who, as a layman, is not bound by medical etiquette. The position of the medical man called in to replace a brother practitioner is always a delicate one. He should not take over the case until his predecessor has definitely received instructions that his services are to be discontinued, and where he has been called to a case owing to the usual medical attendant being away from home he should explain the temporary nature of his services if this is not understood by the patient. But when the position has been regularised he can hardly refuse save in special circumstances, to attend a member of the public requiring his services. *We do not think that the situation described by* our correspondent is one that ought to lead to any unpleasantness whatever between professional brethren.

R. H.—We do not know whether there is any special printed form of the agreement mentioned by our correspondent, but if so we should think that any law stationer would provide one. The agreements in question are, however, generally drawn up in manuscript by a solicitor.

Irish.—Our correspondent might communicate with Mr. William Van Praagh at 11, Fitzroy-square, London, W., or with Mrs. Emil Behnke at 18, Earl's-court-square, London, S.W.

C.—Some of the works in question were sent to this office. Though they are doubtless well-intentioned we do not think that they are suitable for general distribution.

W. K., M.B.—There is no proof that the medical man in question is aware of the use which is being made of his testimonial. His attention might be called to it.

X. Y. Z.—There is none so far as we know.

COMMUNICATIONS not noticed in our *present* issue will receive attentio in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), [illegible] (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George' [illegible] 2.30 P.M.), Middlesex (1.30 P.M.), Westmi [illegible] (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. SATURDAY (14th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (9th).—MEDICAL SOCIETY OF LONDON (11, Chandos street, Cavendish-square W.).—8.30 P.M. Clinical Evening. Cases:—Dr. E. Wynter: (1) Mitral Disease with Pulmonary Regurgitation; (2) Spondylitis Deformans.—Dr. F. J. Poynton: Bilateral Facial Paralysis.—Dr. L. Jones and Mr. C. S. Kingston: Series of Cases of Rodent Ulcer and Malignant Disease treated by the Finsen Light and X Rays.—Dr. S. E. Dore: Cases of Lupus treated by the Finsen Light.—Mr. W. G. Spencer: Scirrhus of the Tongue (third year of exhibition).—Dr. B. Dawson: (1) An Abdominal Case for Diagnosis; (2) Carcinoma of the Stomach.

TUESDAY (10th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. C. Riviere: The Anæmias of Infancy.

[illegible] GREAT BRITAIN (17, Bloomsbury- [illegible] —Mr. E. White: Kino.—Mr. W. [illegible] dine.

[illegible] SOCIETY (London Institution, [illegible] Discussion on Appendicectomy, When and How it should be Performed (opened by Mr. H. L. Barnard). Mr. J. Berry, Mr. G. L. Cheatle, Mr. F. J. Steward, and [illegible]

[illegible] Macnaughton Jones, and Dr. B. Fenwick. Cases by Dr. Hodgson and Dr. I. Parsons.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Lecture:—Mr. R. D. Pedley: Healthy Dentition, [illegible]

[illegible] DICAL OFFICERS [illegible] Paper:— [illegible] Asso- [illegible] Annual [illegible] s shown by the [illegible] cer, Dr. Kelson, [illegible]

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. F. E. Batten: A Case of Myositis Fibrosa.—Dr. G. Newton Pitt: A Case of Measles with Coma.—Dr. Pasteur: A Case of Pernicious Anæmia with Unusual Features.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—5 P.M. Mr. Baldwin: Practical Surgery. (Second Lecture.)

MEDICAL GRADU[illegible] W.C.). 4 P.M. [illegible] Dr. J. Taylor: [illegible] Adults.

TUESDAY (10th).—POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—5 P.M. Dr. R. H. Cole: Alcohol as a Cause of Insanity.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. T. H. Green: Clinique (Medical.) 5.15 P.M. *Dr. J. Taylor: Common Forms of Paralysis in Children and Young Adults.*

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Ferrier: Cases in the Wards.

GLASGOW [illegible] 8 P.M. [illegible] other Pl[illegible] Clinical [illegible] Graduate Course.)

WEDNESDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Russell: Rheumatoid Arthritis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. A. H. Tubby: Clinique (Surgical.) 5.15 P.M. Mr. C. B. Keetley: Unreduced Dislocations.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Perkins: Pneumothorax.

THURSDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Practical Surgery. (Third Lecture.)

MEDICAL GRADUATES [illegible] W.C.).—4 P.M. M[illegible] Mr. H. L. Barnard: [illegible]

SAMARITAN FREE HOS[illegible] 3 P.M. Dr. Lockyer: [illegible]

[illegible] Ormond street, W.C.).— [illegible] LEGE (Tottenham Hos- [illegible] Surgical Diseases of [illegible] (West London Hospital [illegible] ece: Dairies, Cowsheds, and Milkshops.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. Clarke: Clinique (Eye.) 5.15 P.M. Mr. E. P. Paton: Tuberculous Disease of the Knee-joint.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. R. Russell: Myelitis.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be *given to this notice.*

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Che[illegible] "London and Westmin[illegible] should be made payable [illegible] THE LANCET Offices, 42[illegible]

During the week marked copies of the following newspapers have been received: *Daily Messenger (London and Paris), Times, Daily Chronicle, Daily Graphic, Star, Macclesfield Courier Supplement, Daily News, Hertfordshire Mercury, Southern Times and Dorset County Herald, Burnley and District Times, Westminster Gazette, Windsor and Eton Express, Manchester Guardian, City Press, Walsall Advertiser, Herts Advertiser, Reading Mercury, Mining Journal, Surrey Advertiser, &c.*

poet, who began and ended his career at Whitby. In the account of his death by an author who was his contemporary [3] is the earliest mention of hospital accommodation in England. "For when the time of his departure drew near he laboured for the space of 14 days under a bodily infirmity which seemed to prepare the way, yet so moderate that he could talk and walk the whole time. Yeardby was the house to which those that were sick and those who seemed likely to die were carried. He desired the person that attended him, in the evening as the night came on in which he was to depart this life, to make ready a place there for him to take his rest." It is not possible from the account to gather what Caedmon's illness was but the conclusion suggests some disease associated with prolonged physical debility and the relation of his last words bears the mark of truth in the way in which it shows his consciousness of approaching death without knowledge of its immediate nearness. "Then strengthening himself with the heavenly viaticum he made ready for the entrance of another life and asked how near might be the hour when the brothers ought to be wakened to say the nocturnal lauds. They answered, 'It is not long.' Then he, 'Well therefore let us wait that hour,' and signing himself with the sign of the holy cross he laid his head upon the pillow and lightly sleeping so with silence ended life." The third literary glory of the north is the "Historia Ecclesiastica Gentis Anglorum" of Bede, the first great historical book of England. It contains many passages of medical interest. I have already quoted his account of Caedmon. That of St. Ethelreda, abbess of Ely, has a more precise scientific value and also contains the earliest mention by name of a physician in England, "medicus Cynifrid." He attended her in her last illness and had opened an abscess in her neck which was much swollen. It was remembered that she was pleased at the nature of her disease and used to say: "I know that I deserve to bear the weight of my disease on my neck, for I remember that in my girlhood I bore there the very foolish weight of necklaces and I believe that therefore the heavenly mercy wills that I should bear the pain in my neck that thus I may be absolved from the guilt of my silly levity, since now, instead of gold and pearls, the redness and inflammation of a swelling stand out upon my neck." [4] St. Etheldreda died at something over 40 years of age, about the same time as Caedmon, the year 680, and it is clear from this description of a prolonged swelling in the neck ending in suppuration that she was the subject of tuberculosis, so that in this passage of Bede we have evidence that the organism which we know as the tubercle bacillus existed and multiplied in the human body in England in the seventh century. This microscopic growth probably existed long before in our island and has continued to our own time. Kings, who could be no better informed than their most learned subjects and were ignorant of the origin of the prominent symptoms, thought that their touch could cure the swellings which the bacillus produced. One of the greatest characters in our literature has preserved in a note a recollection of this practice: "I was taken to London to be touched for the evil by Queen Anne. I always retained some memory of this journey, though I was then but 30 months old. I remember a boy crying at the palace when I went to be touched. My mother was at Nicholson's, the famous bookseller in Little Britain. I remember a little dark room behind the kitchen where the jack weight fell through a hole in the floor into which I once slipped my leg." [5] It is recorded [6] that King Charles II. touched 92,107 patients for such symptoms, and William Clowes, surgeon to Queen Elizabeth and to St. Bartholomew's Hospital, shows his own view in an account of a patient from Yorkshire whom he saw. In his treatise on the struma he says: "And that I should credit him the more he showed me the angell of golde which her Majesty did put about his neck, truly a cure (as I have said) requireth divine honour and reverence: and heere I doe confidently affirm and steadfastly beleeve that (for the certain cure of this most miserable malady) when all artes and sciences doe faile, her Highnesse is the onely Day starre, peerelesse and without comparison, for whose long life let us all continually pray."

The discovery of the tubercle bacillus by Koch has in our time given the true explanation of the varied phenomena of tuberculosis with which we are first made acquainted, as regards England, by our earliest Saxon historian writing nearly 1200 years ago. Bede's history reveals to us the presence of another micro-organism in England—that of the plague. It seems probable that the epidemic of plague in England in 664, of which Bede tells, reached this country from Ireland and not from the continent. The plague raged in Ireland from August, 663, into the year 664, in which there was an eclipse of the sun on May Day. The epidemic came to England in the early summer of 664, perhaps brought by students returning from Ireland, and seems a curious indication of the fact that there was a greater degree of intercourse between the countries of the Roman Empire and Ireland, which had never formed part of that empire, than between the European kingdoms and Kent which had been utterly cut off from the Roman Empire by the conquests of the Jutes and the Saxons. In Ireland the plague had appeared in the sixth century within a few years of the great epidemic in the time of the Emperor Justinian in Constantinople. About the middle of that century the chronicles record that Tara, which till that time was the residence of the chief king, was abandoned. Diarmait MacCearbhaill, the king, left it and never returned and it was never inhabited again. Its great earthworks remain and attest its former importance, while the rich pastures of the plain of Meath by which it is surrounded show its fitness to be the home of a king whose chief wealth was herds of cattle. In later times its desertion was attributed to the curse of a saint, Ruadhan of Lothra, but an investigation of the facts of his contention with King Diarmait shows that the dispute was amicably settled and that the saint's denunciations, which were after all withdrawn, do not bear the interpretation which was put upon them centuries after they were uttered. The story of the curse is, in fact, only an answer to the question, Why was Tara abandoned? which was given long after the facts had been forgotten. There is no destroyer of tradition greater than an epidemic, which kills off a large part of the generation which might transmit the story. The date of the desertion of Teamhair na righ, Tara of the kings, as the Irish called it, corresponds to that of the introduction into the island of the slow-travelling epidemic of plague which came to it from the city of Justinian and a dwelling-place abandoned because nearly everyone had died there came to be regarded with such dread that even its fine position, far extending view, and rich pastures could not induce future kings to return to it.

It was a little more than 100 years later, in 663, that the ravages of the plague had again been terrific in Ireland. The two kings, another Diarmait and Blathmac, and many of the clergy and laity had died. The deaths in the next year in England were not less startling, for the two chief people in the island, Erconbert, the King of Kent, and Deusdedit, the Archbishop of Canterbury, died on the same day, July 14th, 664.

Thus can we trace the existence in England of a second bacillus, that of the plague, from the history of the Venerable Bede. Again and again in succeeding centuries this bacillus was introduced from abroad and perhaps attained its greatest activity in the reign of King Edward III, destroying thousands in 1348–49. A few years ago, when some tall warehouses with deep foundations were being built in Charterhouse-square, in London, I went to see whether any traces of the dead of this great plague were to be seen and saw many of the skeletons of the victims of the epidemic. But severe as this epidemic was, the general public would in all probability know less of the plague than they do of the Constitutions of Clarendon or the *Quo warranto* but for a great piece of literature in which the less severe though yet terrible visitation of 1665 is described. Defoe's "History of the Plague" is a work of imagination which differs from the travels of Mr. Lemuel Gulliver in having some historical foundation and a different object but resembles the adventures of Robinson Crusoe in owing more to the descriptive powers of the author than to his historical research. Who does not remember Defoe's account of the doors marked with a red cross and the words "Lord have mercy on us," and Solomon Eagle going about "denouncing judgment upon the city in a frightful manner, sometimes quite naked, and with a pan of burning charcoal on his head," and the young woman found dead and deserted in the house alone and that terrible account of the shriek. "Passing through Tokenhouse yard in Lothbury of a sudden a casement violently opened just over my head and a woman gave three frightful screeches and then cried, 'Oh! death, death, death!' in a most inimitable tone and which struck me with horror and chillness in my very blood. There was nobody to be seen in the whole street, neither did any other window open for people had no curiosity now in any case, nor could anybody help one another, so I went on to pass into Bell-alley." And the stopping of the dead carts at doors and the sleeping piper carried away with the dead and waking up on the verge of the plague-pit and the desperation of the infected and the pain of the swellings, the terrible indifference of most to the sufferings of others and the ghastly stillness of many of the streets. No picture could be more distinct.

It is to this unhistorical History of the Plague, which so well illustrates the remarks of Fielding that the works of imagination may have more absolute truth in them than histories, that we owe the fact that almost every child in England has heard of the great plague of London. The quarto of Diemerbröek, the Loimologia of Dr. Nathaniel Hodges, and the Loimographia of the Apothecary Boghurst are perused by physicians, but such is the power of good literature that what England in general knows of the plague is altogether due to Defoe. A very few years ago, walking down Cheapside, not far from the site of the house of Sir Richard Blackmore the physician—he was a respectable physician if an indifferent poet, you will remember the lines of Pope:—

> "The hero William and the Martyr Charles,
> One Knighted Blackmore, and one pensioned Quarles,"—

it was near his door, I say, that I met the medical officer of the Port of London, a gentleman who has great opportunities of acquiring interesting medical facts and whom I therefore asked if he had seen anything worth mentioning lately? "Yes," he said, "the plague has reappeared in London, I have seen two cases on a ship in the river." Since that day I suppose most people concerned in teaching medicine in London have become familiar with the appearance of the plague bacillus under the microscope and to their childish reading of Defoe have added the perusal of many sanitary reports of the terrible epidemic of Poona, of other places in India, and of Hong-Kong. Students have sent home to us specimens of the solid lung of the pneumonia produced by the plague bacillus and of other visceral changes, the dim indications of which are to be found in Hodges and Diemerbröek, and I, whose former pathological touch with this disease was no nearer than the having seen the bones of 1348-49, have known a nurse who died from the plague.

The life of St. Anselm, Archbishop of Canterbury, by Eadmer, a monk of Canterbury who was in the personal service of Anselm and went with him to Italy, contains an illustration, perhaps the earliest in our history, of an important part of medicine, the nursing of the sick. Eadmer[7] speaking of the saint's life at Bec says: "Oh, how many given over in sickness has he brought back to health by his loving care! You felt it, Herewald, helpless old man, when weighed down not only by years but by a severe illness so that you had no control over any part of your physical frame but your tongue and were fed by his hand and were refreshed by wine squeezed from the grapes by one hand into the other, drinking it from his own hand, so that you were restored to health; for, as you used to say, you could relish no other drink nor from any other hand. Anse[illegible] the house of the s[illegible] the brethren and [illegible] uble what he needed." As I am concerned in everything that adds to the glory of St. Bartholomew's Hospital I like to remember that this kind nurse—perhaps I ought rather to say this great saint and theologian—who, to his intellectual ability and metaphysical powers added those practical virtues and that profound consideration for others which are essential in a nurse—consecrated Richard of Belêsme, the Bishop of London, to whose influence with the king St. Bartholomew's Hospital owes its site. The improvement in nursing, though it has made rapid strides in our own day, has been gradual. The Beguines, whose picturesque residences are to be seen at Bruges and Ghent to this day, must have been good nurses if we may trust the account of them which Corporal Trim gives:[8] "By the persuasion of the young woman, continued the Corporal, the cart with the wounded men set off without me; she had assured them I should expire immediately if I was put into the cart. So when I came to myself I found myself in a still quiet cottage, with no one but the young woman, and the peasant and his wife. I was laid across the bed in the corner of the room, with my wounded leg upon a chair, and the young woman beside me holding the corner of her handkerchief dipped in vinegar to my nose in one hand and rubbing my temples with the other. I took her at first for the daughter of the peasant (for it was no inn); so had offered her a little purse with eighteen florins, which my poor brother Tom (here Trim wiped his eyes) had sent me as a token, by a recruit just before he set out for Lisbon. The young woman called the old man and his wife into the room to show them the money, in order to gain me credit for a bed and what little necessaries I should want, till I should be in a condition to be got to the hospital. 'Come, then,' said she, tying up the little purse, 'I'll be your banker; but as that office alone will not keep me employed, I'll be your nurse too.' I thought by her manner of speaking this, as well as by her dress, which I then began to consider more attentively, that the young woman could not be the daughter of the peasant. She was in black down to her toes, with her hair concealed under a cambric border, laid close to her forehead: she was one of those kind of nuns, an' please your honour, of which your honour knows there are a good many in Flanders which they let go loose. 'By thy description, Trim,' said my Uncle Toby, 'I dare say she was a young Beguine, of which there are none to be found anywhere but in the Spanish Netherlands, except at Amsterdam; they differ from nuns in this, that they can quit their cloister if they choose to marry; they visit and take care of the sick by profession.' 'The young Beguine,' continued the Corporal, 'had scarce given herself time to tell me "she would be my nurse," when she hastily turned about to begin the office of one and prepare something for me; and in a short time, though I thought it a long one, she came back with flannels, &c., &c., and having fomented my knee soundly for a couple of hours, &c., and made me a thin basin of [illegible]d me rest, and promised to be [illegible] This wound was received at [illegible] and Sterne, who has left Corporal Trim to be known and admired by all future generations, was certainly intimate with the old soldier who is portrayed in him, and this has always seemed to me to bring Trim near to our own times, for when I was a boy I was often the guest of an old squire in this county whose father, as he told me, had danced with the Reverend Laurence Sterne's daughter at the York ball.

Societies for the nursing and transport of the sick and similar good works, of which the Misericordia of Florence still flourishes and is one of the most ancient, were in existence in the thirteenth century and perhaps earlier. The house of the guild of the Misericordia is now close to the cathedral and on the other side of the way to Giotto's famous tower. Its original house was a few yards nearer the baptistery. The founder was Piero di Luca Borsi, a porter. He had a profound veneration for the name of God and as he sat waiting to be engaged was shocked by the way in which his fellow porters every moment took it in vain. He persuaded them to agree to put a small fine into a box for every oath and the Misericordia arose from the decision of Piero di Luca Borsi and the porters as to how to dispose of the fund which was thus accumulated. The obvious usefulness of the society led to its increase in means and in numbers, and citizens of Florence of all ranks joined it and took their turn of duty in the four quarters of the town. Its organisation is perfect and its work active to this day, and that the kind of help it can give is needed is sufficient claim to its services. The members wear a long gown and hood over their clothes, so that as they conduct an ambulance through the street their personality is not displayed and a Florentine of the most illustrious descent or a well-known public man cannot be distinguished from a porter or labourer who may chance to carry the litter with him or bear the body of a poor man to the mortuary with proper respect, except perhaps by his boots. Every member of the Misericordia takes his turn of duty without fail and if summoned leaves his own table or work or any social engagement when called.

The earliest English hospitals perhaps owe their origin to similar but earlier institutions in Italy. St. Bartholomew's Hospital was founded by Rahere in 1123 after he had made a pilgrimage to Rome and the seal of the hospital which was in use in his time bears two marks of his Italian pilgrimage, for on one side is a figure in the exact dress worn by the Misericordia in Italy to this day, while the reverse is a classical gem which I have the authority of the late Professor Middleton for saying was probably engraved in the third century of our era and which may have been brought from Rome by Rahere himself.

---

[7] Eadmer: De Vita Anselmi, cxli.
[8] Tristram Shandy.

The general destruction of religious societies was no doubt injurious to the nursing of the sick, which became an occupation little esteemed, as may be gathered from numerous passages in English medical writers. The general improvement in the education and training of nurses dates in this country from the public knowledge of the terrible disadvantages of the want of good nurses in the hospitals of the Crimean army. England is at the present day probably ahead of most European countries in the training and general education of nurses, though a great deal yet remains to be done. The little sister in Thackeray's "Adventures of Philip," a book which, if inferior to his greatest works, is yet of interest from the light which it throws on some parts of his own life, is a picture of the best kind of nurse in existence before the time of Florence Nightingale. Having mentioned Thackeray, one is naturally led to think of the great novelist whom he at first made his model. It is curious that as he had studied Fielding so carefully he should have come to admire "Amelia" the most of the three great works of Fielding, and, indeed, that he preferred that novel to "Tom Jones" might be disbelieved did it not rest upon indisputable evidence. In "Amelia" one of the minor characters, Mr. Barnet, is mentioned as having died from polypus of the heart: "the surgeon who opened him after his death advised me that he died of what they call a polypus in his heart."[8] As this expression is not to be found in our official nomenclature of diseases it is worth consideration how a term once so common in daily conversation and in medical writings should have disappeared. The history of polypus of the heart has, of course, a direct relation to Harvey's great discovery of the circulation of the blood. When in 1628 he published his famous "Exercitatio Anatomica de Motu Cordis et Sanguinis" his demonstration was so clear that it was almost universally accepted by the medical world. Dr. Primerose and one or two others did indeed write against it, but they belonged to the group of minds who believe that the world is flat. But it takes a long time for the complete application by men of a great scientific truth. Malpighi about half a century later showed the capillaries which the apparatus of Harvey's time had not enabled him to see and Cowper actually witnessed the movements of the periphery of the circulation in a mammal. The great discovery was completed and confirmed in every particular, yet so imperfect was its application that though James Douglas in 1715 heard a loud murmur synchronous with the beats of the heart as he stood by the bedside of a patient in St. Bartholomew's Hospital and after death saw deformed aortic valves he did not attain to the obvious explanation that the aortic obstruction was the cause of the murmur. It is therefore less astonishing when we find from the numerous theses "De Polypo Cordis" that the firm branching clots often found in the right side of the heart after death were believed to be growths which had formed during life and led to its termination Dr. Matthew Baillie, in 1793, in his "Morbid Anatomy of Diseases," was the first to point out the obvious fact that such a growth would have prevented the circulation, so long did it take for this greatest of discoveries to be thoroughly understood. Indeed, it is hardly too much to say that it was 200 years after the publication of Harvey's book before the whole question was concluded by the general acceptance of our present views on valvular disease; and, indeed, if the understanding of embolus and of hæmorrhagic infarction are to be included several years must be added to the two centuries. "Tom Jones,"—the work which Fielding himself thought the greatest product of his genius and as to which every careful reader shares the admiration of Gibbon who, speaking of the relationship supposed to exist between the Fieldings and the house of Hapsburg, says: "The successors of Charles the Fifth may disdain their brethren of England, but the romance of Tom Jones, that exquisite picture of human manners, will survive the palace of the Escurial and the Imperial Eagle of the House of Austria,"—contains a passage which shows that the discussion of the use of electricity in medicine had begun. Black George the gamekeeper had quieted the scolding of his wife "with a small switch, a remedy of wonderful force as he had often essayed and which the word villain served as a hint for his applying. The whole family were soon reduced to a state of perfect quiet. For the virtue of this medicine, like that of electricity, is often communicated through one person to many others who are not touched by the instrument. To say the truth, as they both operate by friction it may be doubted whether there is not something analogous between them of which Mr. Freke would do well to inquire before he publishes the next edition of his book." Mr. John Freke was surgeon to St. Bartholomew's Hospital, knew Hogarth, and through him was probably acquainted with Fielding. One of the introductory chapters which add so much to the charm of the novel and the succeeding chapter show with how much attention Fielding had read Sydenham's "Treatise on the Gout and Dropsy." The introduction is an invocation of the love of fame and Fielding says: "Comfort me by a solemn assurance that when the little parlour in which I sit at this instant shall be reduced to a worse furnished box I shall be read with honour by those who never knew nor saw me and whom I shall neither know nor see." In the second chapter he returns to the thought. "To have the several elements which compose our names, as Sydenham expresses it, repeated 1000 years hence is a gift beyond the power of title and wealth and is scarce to be purchased unless by the sword and the pen."

The words of Sydenham, somewhat involved in their English version, express his devotion to scientific truth: "And I do not so much inquire whether others are of my opinion as whether what I deliver be agreeable to truth. For what advantage will it be to me after I am dead that eight alphabetical elements, reduced into that order that will compose my name, shall be pronounced by those who can no more frame an idea of me in their minds than I can now conceive what those are to be who will not know such as were dead in the foregoing age." It was the illustration of the nature of posthumous fame on which Fielding reflected, still finding in the hope of that fame an encouragement among the difficulties of life; but the passage of Sydenham goes further and expresses that veneration of truth which the fine lines of Churchill set forth in another phrase—

> "'Tis not the babbling of an idle world,
> Where praise and censure are at random hurled,
> That can the meanest of my thoughts control
> Or change the settled purpose of my soul."

The cerebral effects of raised temperature, which are so much more well marked in children than in adults, are illustrated in the life of an Archbishop of Canterbury whose moral and intellectual qualities were of a high order. St. Dunstan, whose beautiful drawing of himself kneeling at the feet of our Saviour, which is preserved in the Glastonbury MSS. at Oxford and is perhaps the first certainly known picture by a British artist, was brought up as a boy at Glastonbury Abbey. The great church was undergoing repair at the time when he chanced to have a febrile illness, perhaps a pneumonic consolidation of part of one lung. He climbed up on to the roof of the church and was there seen by a person who wisely did not suddenly disturb him. In time the boy climbed safely down unconscious of his dangerous journey. A boy whom I chanced to know, who was at a preparatory school a few years ago and was in a febrile condition connected with a sore throat, climbed out of an upstairs window, down a water pipe, crossed a piece of ground, pulled up some small trees, and returned without any definite object and unconscious of where he had been. A young adult labourer with pneumonia, in the course of his delirium rose from bed, walked the length of the room in which he was, got out of a small window at the end, and dropped some 40 feet to the ground. By an uncommon good fortune he escaped both fracture and internal injury and in course of time recovered. He had no suicidal intention or recollection of having left his bed. Thus an incident which might seem an exaggeration or an improbability to a general reader, when considered in the light of medical experience is seen to be a truthful statement of fact.

The lives of saints contain many passages interesting to a student in medicine the accuracy of which may often justly be considered as evidence of the general veracity of the narrative. A curious example of the uncertainty which prevailed as to the function of the blood occurs in Dryden's Epistle to Dr. Charlton, published in 1662, the finest tribute which science has obtained in English from the poets:—

> "The circling streams, once thought but pools of blood,
> Whether life's fuel, or the body's food,
> From dark oblivion Harvey's name shall save."

---

[8] Amelia, Book vii., c. 9.

The poems of Donne, with his taste f
allusions, contain several examples drawn fr
scientific notions of his time, and in a curio
"The Will" he mentions his medical books:—

"To him for whom the passing bell next tolls
I give my physic books."

His poems contain also some allusions curious from their relation to things with which men were then familiar, such as the line—

"Racked corpses make but ill anatomies,"

which brings to our mind the political criminal who after torture and death in prison or on the gallows was handed over for dissection.

The greatest of all our authors, of course, contains many passages which show that he had thought on medicine as on everything else and these repay consideration, but they would require an essay to themselves. My object in this address has been to show how we who are acquainted with medicine may use literature as one of the many means of improving ourselves in our own subject. I have therefore said nothing of the errors of authors who have approached medical subjects nor alluded to those passages of literature which merely relate to the histories or characters of physicians. These afford abundant material worth consideration and some of them, like the account of the doctor of physic in the "Canterbury Tales," which describes his pathological views as well as his turn of mind, his dress and his library, almost belong to the actual illustration of medical study and observations in our literature.

As to the relations between physicians and the world of letters, how much there is that contributes to the permanent honour of our profession in Swift, in Johnson, and in many others. I began by showing how a knowledge of medicine was long ago thought a part of a complete education and in the altered conditions of our times I like to feel that our laborious studies, besides their usefulness, as we apply their results to mankind, also make us part of the learned world. We cannot but value the honours which have been conferred by literature upon medicine, such as the verses of Cowper to one of my predecessors at St. Bartholomew's Hospital, Dr. Austen:—

"Austen! accept a grateful verse from me,

[illegible]

A Lecture

ON

OCCUPATION AS A CAUSE OF LUNG DISEASE.

Delivered at the Mount Vernon Hospital for Consumption, London, on Oct. 15th, 1903,

BY THOMAS OLIVER, M.A. DURH., M.D.
GLASG., LL.D., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

GENTLEMEN,—When honoured with an invitation from the subcommittee of the Mount Vernon Hospital to deliver the opening lecture of the post graduate course of study for this session, I felt that while I was not in a position to convey any fresh information I might yet accomplish some useful purpose if I refreshed your memory by presenting old facts in the light of recent pathology. I have chosen as the subject of this lecture "Occupation as a Cause of Lung Disease" and while in the main my remarks will apply to phthisis they will of necessity include affections of the respiratory tract generally. It is gratifying to know that the mortality from tuberculous phthisis in this country has for many years past been declining. For each million of the death-rate began anterior to the discovery of the tubercle bacillus by Koch there can therefore be no causal relationship, as has sometimes been assumed, between the two. More exact knowledge of the infectiousness of tuberculous phthisis has certainly strengthened the hands of the physician so far as treatment is concerned. If this is the case in ordinary phthisis then to the improved conditions under which work is carried on in the coal mines of this country must be attributed the great diminution in the death-rate of miners from pulmonary disease. Since, however, statistics still show that the mortality from phthisis in people who follow certain trades is much greater than in others there can be no doubt of the causal relationship between occupation and pulmonary disease and of dust being the *causa causans.* So much is this the case that to a group of lung diseases characterised by excessive development of fibrous tissue throughout the lungs the term "pneumoconiosis," introduced by Zenker, is still applied and according to the character of the dust so are the pulmonary lesions described as anthracosis, silicosis, siderosis, &c. These words were framed before Koch's discovery of the microbe of tubercle. Most of the opinions held by medical men to-day in regard to pneumoconiosis are pretty much those that prevailed previously to the discovery of the tubercle bacillus. It is worth our while therefore to review the subject of pneumoconiosis in the light of the knowledge we now possess of the specific micro-organism of tubercle.

In 1860 Sir John Simon, in drawing attention to statistics compiled by Dr. Greenhow, remarked that "certain diseases, which among them make up fully one-half of our annual mortality, are fatal in widely different degrees in different districts of England."[1] The death-rates of the adult population by pulmonary diseases had ranged, as regards grown-up men, from 221 and 306 to 1298 and 1440 per 100,000 of the population. Death-rates from phthisis alone among grown-up women had ranged from 229 to 558, and "to account for so unequal a distribution of particular kinds of death there must prevail almost corresponding inequalities in the distribution of the causes of disease." The problem discussed at this particular period was why in some districts in England grown-up men and women should die from certain diseases of the lung three, four, or even six times as abundantly as in other districts. As regards tuberculous phthisis and bronchitis it was felt that the large mortality from these two diseases in particular districts was influenced by the industrial relations of the people, so that when comparisons were made between agricultural and manufacturing populations it was found that "in proportion as the male and female populations are severally attracted to in-door branches of industry, other things being equal, their respective death-rates by lung disease increased."[2] Dr. Baly of Millbank Penitentiary experience had just published his essay on "Diseases of Prisons" and in it had drawn attention to the extremely high death-rate of convicts from lung disease, which he attributed to the operation both of physical and moral causes. On making a comparison between the life of a worker in a textile factory or other in door occupation with that of a prisoner it was seen that in textile factories there are the same monotony, seclusion from air and sunshine, also the breathing of impure air for the greater part of the day, all of which depress the vital resistance of the individual and predispose him to catching cold.

In 1860 it was demonstrated that among the suffering districts there were places which were the chief seats of metal mining, of metal manufacture, and of pottery manufacture, and that in these places the predominant lung disease was at least primarily bronchitis, in regard to which two kinds of occupation had long been recognised as hurtful—viz.: (1) those that give rise to mechanical or chemical irritation of the air passages by dust, grit, or fluff being diffused through the atmosphere; and (2) those in which the operatives are exposed to abrupt changes of temperature. The report showed with reference to phthisis and bronchitis and the influence of occupation "that the high death-rate from lung diseases belonged specially according to the occupation to the men or to the women of the district; that it was sometimes nearly twice as high for the employed sex as for the unemployed; and that of debility, cough, and difficulty of breathing on exertion but there is an absence of hæmoptysis, of night sweats, and of rise of temperature. Physical signs of consolidation of the lung develop, followed by those of excavation. Death often comes suddenly and is due to heart failure. The relation of ganister miners' phthisis and tuberculous disease of the lungs may be dealt with, according to Dr. Robertshaw, under three heads: (1) those cases in which after the fibroid change has damaged the lungs true tuberculous phthisis plays the chief part; (2) those in which tubercle is found but which is only very secondary to the fibroid disease; and (3) those in which there is no tubercle at all, the disease being entirely due to the fibroid change brought about by the ganister dust. Dr. Robertshaw is of the opinion that the majority of the cases fall under the last two headings and that few of the cases are mainly tuberculous partly on account of their chronicity and partly owing to the fact that the pulmonary lesions found after death are not exactly the same as those met with in chronic tuberculous disease of the lung.

---

[1] Public Health Reports, John Simon, vol. ii., p. 19.
[2] Ibid., p. 20.

Portions of the lungs of two ganister miners who had died from silicosis were submitted to Dr. F. W. Andrewes, pathologist to St. Bartholomew's Hospital.[11] His examination proved beyond doubt the correctness of Dr. Greenhow's conclusions published many years ago in regard to dust diseases of the lungs—viz., the presence of nodular consolidation of the lung, deposition of black mineral matter around the bronchial tubes, arteries, and veins, and the fact that while the development of tuberculous phthisis is intimately associated with, it is yet independent of, the lesions produced by dust. Dr. Andrewes at the close of his admirable report of the second case says: "I conclude from the examination of these lungs that the primary changes are dependent upon the chronic irritation of an inhaled mineral dust which, being absorbed by the lymphatics, gave rise to a fibrosis which is lymphatic in its distribution in its earlier stages though it subsequently extends to large areas of lung tissue. Upon this fibrosis a secondary tuberculosis has been grafted; the tuberculous changes are more widespread and obvious in this case than in Case 1, but there is no evidence that the tuberculous disease is primary."

Coal Miners' Phthisis or Anthracosis.

I have so recently discussed this subject elsewhere[12] that I shall only briefly allude to it now. Coal miners' phthisis, formerly of common occurrence, is now rarely met with owing to the improved ventilation of the mines. So far as lung disease is concerned coal mining in this country is comparatively speaking a healthy occupation. When colliers become the subjects of bronchial and pulmonary catarrh they bring up large quantities of a black spit; it is thin and inky in colour and on microscopical examination is found to contain large cells studded with granules of coal. An interesting point in regard to anthracosis is that the lungs may be deeply pigmented for years without any signs of ill health and that there are some forms of coal dust which do very little harm to the lungs compared with others. The larger the amount of stony particles in coal the greater is the tendency for the lung to suffer. Virgin coal contains no micro-organisms. How far the particles of carbon exercise, as some writers maintain, an antiseptic influence upon the lung I am not prepared to say.

Gold Miners' Phthisis.

"Gold miners' phthisis" formed the title of a paper by me which was published in The Lancet.[13] To this subject, therefore, I must only briefly allude. In consequence of working in mines the air of which is impregnated by dust given off from the percussion drills used for boring the rock, also the absence of any satisfactory system of ventilation, Transvaal gold miners are a short lived class of men. As an illustration of the disastrous results of dust in ordinary rock mining Mr. Francis Fox, M.Inst.C.E., says that he was personally connected with a certain heading which was being driven by a gang of 16 miners, all fine, powerful fellows, and yet within a comparatively short time every one of them had died from consumption. Without giving absolute credence to the statement that the average life of a rock driller in England is eight years and in South Africa only four we cannot but, on the other hand, attribute a tendency to miners' phthisis on the Rand to the fact that as the rock drillers in South Africa work on contract the eagerness of the men to earn from £60 to £70 a month deters them from waiting until the dust has settled after an explosion and consequently very shortly after a blast has taken place the miners go into the poisonous and dusty atmosphere. Although dust is generally admitted to be the cause of silicosis in the Rand miner there is a belief that the impure atmosphere in which the miner works is also responsible for part of the illness. The air of the South African mines contains a high percentage of carbon monoxide and carbon dioxide and is laden with the nitrous fumes given off by the use of the higher explosives. When miners become "gassed" the symptoms generally point to an acute intoxication which soon subsides on the men being brought to the surface. As in some forms of gas poisoning—e.g., nitric peroxide—there is found after death acute congestion of the lungs it is a point worth investigating whether as a consequence of the repeated inhalation of an atmosphere poisoned by the gases already mentioned, but not present in sufficient quantity to cause intoxication, there may not be induced a diminution of the vital resistance of the lung followed by structural alterations.

In December of last year Lord Milner appointed a commission composed of mining engineers, chemists, and medical men "(1) to inquire into the extent to which miners' phthisis prevails; (2) to ascertain the cause of the disease; and (3) to make recommendations as to the preventive and curative measures which should be adopted by legislation or otherwise.[14] The commission reported that miners' phthisis is largely found in the rock-drill men of the Witwatersrand district. Of 4403 miners working underground in the gold mines of the Witwatersrand 1210 were medically examined by the commission, and of these 187, or 15·4 per cent., were found to be suffering from the disease, while a further 88 were suspected cases. Of these 187 men, 20 gave a family history with a tendency to phthisis. That miners' phthisis is particularly prevalent in rock drillers whose occupation is admitted to be extremely dusty is shown by the fact that 172, or 91·98 per cent., of the men had been employed on rock drills. Out of 1377 rock drill miners employed on the Witwatersrand it is stated that 225, or 16·34 per cent., had died during the two and a half years immediately preceding the war. All the evidence, practically speaking, shows that the inhalation of minute particles of inorganic matter is the primary and exciting cause of the malady. One point to which attention is drawn, and very properly too, for it applies pretty well to all forms of pneumoconiosis, is the difficulty of diagnosing the disease in its earliest stages; also this very important fact that once the disease is extensively developed it gradually but surely destroys life. The medical evidence tendered to the commission did not disclose the existence of an appreciable amount of tuberculous disease among the miners. A similar opinion was expressed by me more than a year ago, which recent experience has confirmed. The lungs of a Rand miner who died a few months ago and whom I had watched carefully during the greater part of a year were perfectly black and consolidated but free from tubercle. At his death this miner was 31 years of age. A few months before he died I asked him to supply me from memory with the names and ages of men who had worked with him in the Transvaal mines and who had died from phthisis. He knew of 16 men who had succumbed between the ages of 35 and 45 years after having worked for five or six years; also of 17 men, aged from 28 to 35 years, who had died, having worked on an average from four to five years. These and the other statistics I have given show what a fatal calling rock drilling on the Rand is and of the immediate necessity for introducing into South African mines those precautionary measures which have made coal mining in our own country a comparatively speaking healthy industry.

Metallic Trades: File Cutting by Hand, Steel Grinding, &c.

Of the various Sheffield trades file cutting by hand is admitted to be one of the most unhealthy. Apart from the risks of lead poisoning and its attendant evils, file cutters have a mortality from pulmonary phthisis far above that met with in most trades. Dr. John Robertson, formerly medical officer of health of Sheffield and now of Birmingham, has been good enough to favour me with some statistics. Taking the mortality returns from phthisis and respiratory diseases of several occupations as supplied in Part 2 of the Supplement issued by the Registrar General to his fifty-fifth annual report it will be observed that in only three other occupations is the mortality from phthisis and diseases of the respiratory system greater than it is amongst file cutters and that of these three other occupations one is that of cutler, scissor maker, &c., including grinders, and that when the mortality amongst agricultural labourers is taken as unity the mortality from these diseases amongst file cutters is found to be really four times as great.

---

[11] Ibid., p. 493.

[12] British Medical Association Meeting, Swansea, August, 1903.

[13] The Lancet, June 14th, 1902, p. 1677.

[14] Report of the Miners' Phthisis Commission, 1902-03, Pretoria.

Taking for 1889 the mortality figures of phthisis in agriculturists as 106 and diseases of the respiratory system as 115, the mortality figure from these diseases in file makers was 402 and 423 respectively, while in cutlers and scissor makers it was 382 and 518. Taking the mortality returns for Sheffield for 1902 there were registered the deaths of 116 steel grinders; of these 60 were certified as due to phthisis, equal to 51 per cent.; of 116 cutlers who died 20 succumbed to phthisis, equal to 17 per cent.; of 69 file cutters nine died from phthisis, equal to 13 per cent.; while of 321 labourers of various kinds who died in Sheffield during 1902 40 died from phthisis, equal to 12 per cent. High as is the mortality from phthisis among the steel and knife grinders of Sheffield it is not so high as that in Germany. In 1898 the Government factory department at Düsseldorf issued a special order in consequence of the prevalence of phthisis among knife grinders. During "the ten years 1885-95, 72·5 per cent. of the deaths among knife grinders in the Solingen district were due to phthisis, against 35·3 per cent. for the rest of the population over 14 years of age, and an official medical examination showed that out of 1250 grinders only 85 were over 45 years of age."[15] What makes knife and scissor grinding such a dangerous occupation from a phthisis point of view is the fact that the grinding is usually done upon a dry stone. Hand file cutting, on the other hand, is dangerous, not so much because it is a dusty trade as that it is generally carried on under extremely bad hygienic conditions. The shops in which the men work are small, low-roofed buildings. They are generally situated at the rear of other houses and usually look into a courtyard. The shops have simply an earthen floor, are overcrowded, have no fireplace as a rule, and as the work is cold ventilation by an open window is never encouraged. While the trade is a dusty one the circumstances in which it is carried on favour infection by tubercle. Hand file cutters are notoriously a dirty class; very few of the men pay any attention to personal cleanliness. Add to the harmful influences of working in a dusty atmosphere and breathing an impure air, the possibility of tuberculous infection owing to the contaminated state of the earthen floor by expectoration, an the high death-rate from phthisis is not only explained but the lines are indicated along which the high mortality may be diminished.

Dr. Arthur J. Hall of Sheffield has been good enough to send to me for inspection the lungs of a steel grinder who died from phthisis, also some microscopical sections. The lungs, which are greyish-blue in colour, show very distinct excess of fibrous tissue with here and there in the upper lobes cavities of various sizes in all probability due, as Dr. Hall states, to tuberculous infection. On examining sections of the lung, particles of dust are observed to be freely but unevenly distributed throughout the fibrotic tissue. It is difficult to say how far these granules are particles of stone or particles of steel. In the ordinary process of wet grinding the quantity of dust given off from a stone is not great, but when the men are preparing a new grindstone and are what is called "racing" it a considerable amount of dust is given off.

Potters' Rot; Potters' Asthma.

The liability of potters to pulmonary disease has for centuries been known. Ramazini drew attention to it in 1750. Sir Charles Hastings in his work on Bronchitis published in the second decade of last century makes special mention of it. Dr. Greenhow found that potters' phthisis or asthma resembled that to which colliers, razor grinders, and other operatives who inhale dust are liable. The pottery workers who suffer most are the china scourers, flat pressers, and hollow ware pressers, but workers in some of the other processes are not exempt. China scouring is probably the most dangerous. True potters' phthisis, according to Dr. S. King Alcock of Burslem, is the result of inhalation of clay dust. This, however, is a condition which the Home Office has almost improved out of existence. The main constituents of the clay used in pottery manufacture are silica and alumina; on the other hand, in the dust given off during china scouring there are fine particles of flint. Dr. Greenhow regarded the malady as a chronic bronchial affection to which either pneumonia or tuberculous phthisis might be added. The disease is therefore often mixed in character, being partly of the nature of a bronchial affection excited by a mechanical irritant, dust, and partly tuberculous. Dr. Alcock considers the sequence of pathological events to be an irritation fibrosis which may sooner or later cause fatal results by its displacement of true lung tissue and concomitant want of aeration or by becoming the seat of tuberculous infection. It is the siliceous constituent of potters' clay that accounts for the mischief caused to the lungs. The late Dr. J. T. Arlidge[16] maintained that the particular branch of the industry that suffers most is that in which the largest amount of dust is evolved—hence the greater frequency of lung lesions among turners and pressers than among throwers; but the strongest example of injury to health from dust is found in the case of the china scourers, always women, who have to brush and to beat off the dust from the china ware after it has been fired and is being removed from the saggars. Potters' phthisis when uncomplicated by tubercle "advances imperceptibly and without constitutional disturbance. One of its first symptoms is a clearing cough on first rising, but soon to be met with on any change of temperature and accompanied by shortness of breath. Hæmoptysis does not usher in the malady and more frequently than not never makes its appearance. The appetite and the general bodily functions remain long intact; there is no febrile action, no accelerated pulse, no hectic, and no rapid emaciation."[17] By degrees the cough becomes more paroxysmal and is even more violent than that of ordinary phthisis, signs of consolidation are detected, and, as in all forms of pneumoconiosis, an urgency of dyspnœa is developed out of all proportion to the ascertained extent of consolidated lung. Even in advanced cases Dr. Arlidge found that the general aspect and the physiognomy in potters' phthisis differ from those of tuberculous phthisis. "The features are rather those of asthmatical subjects; the countenance is not pinched or sunken; the lustrous eye, the often pink and transparent skin of phthisis, the clubbed finger ends, and the incurved nails are wanting." As might be expected, the advent of tuberculous disease in the lung will alter the picture of fibrosis just drawn. Dr. Arlidge found the mean age at death of male potters, aged 20 years and upwards, to be 46½ years, whilst that of non-potters was 54 years, and that while potters died from consumption in the proportion of 12 97 per cent., in non-potters the index only reached 9 20 per cent. The excessive mortality of pottery workers is therefore mainly due to phthisis and disease of the respiratory organs. "The mortality of potters from bronchitis is more than four times as high and that from other respiratory diseases is three times as high as the mortality of occupied males in the aggregate. Potters succumb to non-tuberculous disease of the lungs much more rapidly than they do to tubercular phthisis, and it is certain that much of the so-called potters' phthisis ought properly to be called cirrhosis of the lungs."[18]

During one of my official visits to France while acting as medical expert to the Home Office I had the opportunity of visiting some of the porcelain factories in Limoges, where I was informed that a larger proportion of workers in the china factories die from phthisis and disease of the lungs than persons engaged in other trades. During 1887, of 75 deaths registered in Limoges as occurring among porcelain makers, 36 were due to phthisis, and in 1888 of 30 porcelain makers examined by Dr. Raymondaud of the Limoges School of Medicine 20 were found to be suffering from pulmonary consumption and two had had pneumonia. Professor Lemaistre, with whom I had the opportunity of discussing this subject, found on analysing the air of the workshops that it contained particles of granite, flint, dried glaze, charcoal, &c., also that the air in the workshops which the brushers-off, the finishers, and the porcelain makers breathed contained 640,000,000 particles of dust to the cubic metre. It is to the presence of this large number of particles of dust in the air that is attributed the frequency of bronchitis and of pulmonary disease. The average age at death of men from fibroid phthisis in the potteries of Limoges is 43 years and of women 38 years.[19]

Gases.

Time will not permit of me dealing with occupation lung disease caused by the inhalation of vegetable dust and it will only allow me briefly to touch upon those maladies that are caused by gases. Most of the ill effects that follow inhalation of gases by men when at work partake too much of the nature of acute intoxication and are rather illustrations of rapid death due to the entrance of poison by the lung than of disease of the lung. In death caused by inhalation of nickel carbonyl there has generally been found acute congestion of the lungs; so, too, this arises as a consequence of breathing nitric peroxide formed after explosion of nitrous compounds. In the case of men engaged in chemical works in manufacturing caustic soda and bleaching powder, &c., the risks are immediate and remote. In what is known as the Leblanc process Mr. A. P. Laurie[20] draws attention to the large quantities of hydrochloric acid gas that are liberated. This gas has a suffocating and irritating effect when breathed and if given off in large quantities respiration becomes impossible. When breathed in even small quantities over a lengthened period it is injurious. Although the workmen protect themselves with a flannel muffler tied over the face the acid fumes cause the teeth to rot. Were it not for a similar protection worn by the bleach packer he could not stand in the chlorine chamber more than a few seconds. The effects of chlorine are irritant and suffocative, and although these effects are usually temporary they yet lay the seeds of bronchitis and emphysema. Chemical workers have a comparatively low death-rate from phthisis—162 as against 402 of file makers and 185 of occupied males; but they have a very high mortality from diseases of the respiratory system—viz, 502 as against 423 file makers and 221 occupied males. The mortality from bronchitis in chemical workers is 249, as against 83 for occupied males. This figure 249 is the largest of all ordinary trades and, so far as diseases of the respiratory system are concerned, there are only two industries in which higher figures are given—viz., cutlers 518 and pottery workers 668. Laurie gives it as the opinion of medical men in St. Helen's that such gases in the air as sulphur dioxide, hydrochloric acid, nitrous fumes, and chlorine are beneficial to phthisical patients, for not only is phthisis rare in that town, but when present the progress of the disease is slow. A similar opinion has been expressed by Dr. James Beatty of Belfast who attributes the low death-rate from phthisis in chemical workers to some antiseptic action of such gases as sulphur dioxide and chlorine.

Pathology of Pneumoconiosis.

The particular structural alteration of the lung found in pneumoconiosis is an excess of fibrous tissue which transforms the spongy texture into material of a solid nature. The bronchi are seen to be wider than usual, with thickened walls, and from them there radiate outwards to the surface of the lung thick strands of fibrous tissue. Occasionally small cavities are seen. The pleura at places may be thickened and adherent. Although Laennec described cirrhosis of the lung it was Corrigan of Dublin who revived interest in the malady in 1838, who demonstrated the association of pulmonary fibrosis with dilatation of the bronchial tubes and who spoke of the lesion as interstitial pneumonia. Local irritation preceded by diminished resistance is believed to be capable of inducing this form of chronic inflammation. Fibrotic reaction to irritation is not so strongly marked in the child as in the adult, and it is probable, although it is difficult to prove the statement, that in the case of adults some persons exhibit a greater idiosyncrasy to fibrosis than others. A great deal depends, too, for example upon the character of the dust that may be inhaled. In anthracosis miners may have inhaled for years particles of coal dust without injury. Claisse and Joué[21] did not find beyond the discolouration any marked structural alteration in the lungs of animals that had breathed for a short time daily during several months smoke given off from burning turpentine. The particles of carbon in their experiments were too soft and altogether different from the hard angular particles of stone or metal found in the lungs of the Transvaal gold miner or the Sheffield steel grinder. The pulmonary parenchyma can tolerate the presence of certain particles but not that of others, and when pathological changes occur it is not always easy to say how much of these is the result of the direct action of dust itself or of superadded infection. To some writers there is no such disease as simple inflammatory pneumoconiosis; all are the result of secondary infection. Particles of dust, if small and soft, may penetrate the walls of the alveoli and produce no effects, but if they are hard, angular, and large they wound the tissues and by irritating them create a soil upon which microbes may flourish and cause secondary infection.

Previous diseases of the lung may be a cause of fibrosis as is seen in acute pneumonia becoming chronic. What is it that brings about the development of an excess of fibrous tissue in this latter affection? We know how the previous debility of a patient gives a bias to his illness and how the presence of microbes in the lung other than pneumococci may influence his ultimate recovery. The presence of such other microbes as those of influenza or of tubercle, also of streptococci, may convert an acute into a chronic or interstitial pneumonia and there is every reason to believe that repeated catarrhs and the presence of irritant dust that has been inhaled will induce the same results. What is the fibrosis that occurs in all these circumstances? Is it an inflammatory or a dystrophic lesion? The supporters of the inflammatory theory hold that the exudate which has been thrown out is not absorbed and therefore it plays the part of a foreign body which irritates the connective tissue and causes it to become infiltrated with round cells that ultimately fibrillate. According to the dystrophic theory, on the other hand, a diseased portion of the lung becomes useless in function, loses its structural character, and becomes replaced by a low form of fibrous tissue which keeps encroaching upon the pulmonary parenchyma and ultimately replaces the spongy substance of an air-filled organ by material of a more solid nature.

Microscopic Anatomy.

The narrow openings of the nares, the abundant secretions of the nasal, laryngeal, and tracheal mucous membranes, as well as the activity of the ciliated epithelium which lines the respiratory tract are natural barriers to dust reaching the lungs and yet in time, if the inhalation of dust is frequently repeated and the atmosphere is in any way thick, these fail to prevent its entrance. In the case of a small, rough, long-haired, terrier dog, whose mouth and nose were pretty well concealed by hair and who was simply placed in a coal-dust atmosphere for an hour or so every day or two during a period of four months, the lungs were found to be studded with bluish-black particles of pigment and the bronchial glands were inky-black. As the conditions under which this animal was placed were exactly the same as those of coal miners when at work, only perhaps somewhat exaggerated, the lesions therefore may be taken to represent fairly accurately the development of uncomplicated anthracosis in the coal miner. Any pathological remarks made in regard to this experimental anthracosis may, I think, be equally applied to pneumoconiosis in general. As already mentioned there are in coal dust two constituents to be considered—viz., the comparatively soft carbon and the stony particles to which the carbon adheres. It is the stony particles which cause the greatest amount of irritation to the lung when inhaled. In addition to signs of reactive inflammation there can be observed in microscopical sections of the lung either massed together or discrete, numerous particles of dust, also numerous large phagocytic cells laden with minute granules of coal in the alveolar wall and surrounded in places by masses of small round cells. Whether these phagocytes are normal habitants of the pulmonary alveoli, altered epithelial cells, or enlarged leucocytes stimulated into activity by the presence of dust in the lung and overfilling of the capillaries in consequence I am not prepared to say. They are found *par excellence* in certain catarrhal conditions—e.g., broncho-pneumonia. These wandering cells take up coal and other dust with great rapidity. Many of them make their way to the bronchial glands where they either unload themselves of their burden or in the act of disintegration discharge their contents. In one of the sections of a bronchial gland this is quite apparent. A few of these phagocytic cells can also be seen in the small bronchi and although the thick basement membrane of the large bronchial tubes forms an effective barrier to the entrance of dust *per se*, yet here and there in the sections can be seen phagocytic cells penetrating the mucous membrane of the smallest bronchi and carrying in with them considerable quantities of coal dust. A few of the minute bronchioles have become occluded by particles of dust and the parts of the lung supplied by them are in a condition of atelectasis. Around the walls of the infundibula, in the alveolar walls, also in and around the mucous membrane of the smallest bronchi, may be observed minute particles of coal dust either lying free or deposited in the interior of the macrophages already alluded to. The facts that these pigmented wandering cells can be detected carrying off dust in the direction of the bronchial glands and that they are met with in lungs that have not been specially exposed to dust show that they are scavengers and that in thus operating they are one of nature's methods of clearing the lungs of dust.

[20] Dangerous Trades, by T. Oliver; article on Chemical Trades, Laurie, p 568, &c.

[21] Recherches Expérimentales sur les Pneumoconiosis, P. Claisse et O. Joué, Archives de Médecine Expérimentale et d'Anatomie Pathologique, Paris, 1897, p. 205.

In the later stages of pneumoconiosis the round cells thrown out under the influence of inflammation, which lie at first loosely in the pulmonary parenchyma, ultimately become transformed into fibrous tissue which assumes a laminated form around the vessels and gives to the lungs the nodulated and consolidated feeling experienced on handling and cutting into these organs. The newly formed fibrous tissue is at places observed to be strewn with minute particles of pigment and as these are usually extremely minute they must have been deposited there, many of them, by the wandering cells during their disruption, while the harder and larger particles of angular form have been deposited without the influence of cells. However much these larger particles of inorganic matter may by themselves have been a source of direct irritation to the lung and a cause of reactive inflammation, it is more than probable that the phagocytes laden with particles of dust throw off, just as bacilli evolve toxins and leucocytes alexins, some material which acts as a poison and an irritant to the connective tissue of the lung. The sclerogenic power of tubercle bacilli and of their toxins is well known, and if these micro-organisms are capable of inducing well-marked fibrosis of an organ there is no reason why the large leucocytes in the lung in abnormal circumstances may not secrete material that also stimulates into activity the reproduction of the connective-tissue cells. In the lung it is difficult to say how much of the reactive inflammation is the result of the direct irritation by dust and how much the result of laden phagocytes, but that a sclerogenic power is exercised by the dust-laden phagocytes is shown by the fibrosis that has taken place in the peribronchial glands of a patient who died from steel grinders' phthisis. The bronchial glands in that patient had undergone a change of structure akin to that in the lungs. The cause of the fibrosis in this man was probably the disruption of dust-laden cells in the glands and the liberation of pigment particles, but on this, as on several other points in the pathology of pneumoconiosis, it is well not to dogmatise too absolutely at present.[22]

THE OPERATIVE TREATMENT OF TUBERCULOUS GLANDS OF THE NECK.

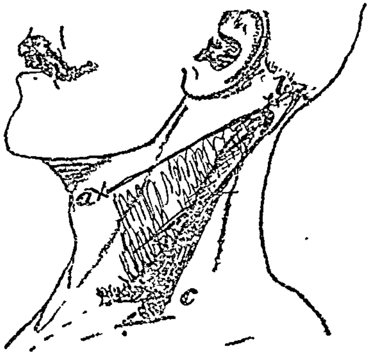
BY W. GREENWOOD SUTCLIFFE, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ROYAL SEA-BATHING HOSPITAL, MARGATE, AND TO THE MARGATE COTTAGE HOSPITAL.

So much has been written on this subject that it is difficult to say anything that has not already been published by surgeons of wider experience and greater knowledge, but as a very large number of these cases are seen in Margate, at the Royal Sea-Bathing Hospital and elsewhere, many of which have been operated upon by other surgeons, a few remarks founded on that experience may even now not be out of place.

It is generally recognised that climatic and hygienic treatment with a liberal dietary are important factors in securing the diminution in size, and in some few cases the actual disappearance, of the glands, though it is but seldom in an old established case that their removal is to be effected by other than surgical means, and it is with those cases that I propose to deal. In undertaking an operation on tuberculous glands, especially in the neck, several points are to be considered. First, the desirability of completely clearing out the glands, however deeply situated, so as to avoid the disappointment of the patient at the recurrences that are so often seen. The second point is that all operations should be planned with a view to make the resulting scars as little visible as possible. The third point is that as these glands are seldom if ever in themselves fatal and are only rarely followed by tuberculous general infection, the operation should be attended with as little risk to the patient and with as little damage to the vessels and nerves of the neck as is consistent with a complete removal of the disease. No routine incision or operation can be laid down for all cases for the obvious reason that the groups of glands affected vary so much in size and in situation. In some instances a few superficial glands only are affected and their removal is an extremely simple matter, but such uncomplicated conditions form a very small proportion of those that are sent to Margate.

The older incision along the anterior border of the sterno-mastoid, especially when it extends along its whole length, leaves a most unsightly scar, and the incisions are now always planned so as to fall as far as possible into a natural sulcus of the skin or where the mark can be concealed easily by the hair or dress. The incision usually adopted for the most commonly enlarged set of glands, that in the anterior triangle beneath the sterno-mastoid, is one following accurately the creases of the neck as first suggested by Kocher of Berne. In most necks two slight grooves can be made out in the skin running obliquely across the neck from the thyro-hyoid region to below the lobe of the ear, and one of these folds is selected as the site of the incision according to the position of the larger part of the glands to be removed. Through this transverse incision fairly large masses are readily accessible, especially when both edges of the cut are freed from the underlying structures for about an inch or so.

Where the greater part of the mass is in the posterior triangle an additional longitudinal incision is made from the posterior edge of the swelling downwards and obliquely forwards so as to hit the posterior border of the sterno-mastoid about its middle. In this case the transverse incision need not be prolonged so far backwards. In very large cases where apparently all the glands in the neck are



U[illegible] incision for very large cases. The flap *a b c* is [illegible] r line is [illegible] ne smaller

diseased the scar that shows the least is to be made by turning a flap forwards and downwards. The transverse incision is carried well backwards to a little below the posterior border of the mastoid process, from that a longitudinal incision is carried down obliquely so as to reach the sterno-mastoid a little above the clavicle, and the whole of this triangular flap is dissected up and thrown forwards. When replaced after removal of the masses of glands, the posterior longitudinal cut is nearly all out of sight and the transverse scar shows very little—so much so that on seeing the patients some months after it would hardly be credited that such an extensive dissection had been carried out—and while the operation is being done the whole dangerous area is under direct control. These incisions are necessarily modified by the presence of broken-down skin, superficial abscesses, and by the existence of scars of previous operations. It would seem obvious that where a scar already exists that its site should be utilised for the new incision, the old scar, if fibrous and unsightly, being removed at the same time. But this does not appear to be the universal practice in the metropolitan hospitals, as there was recently in the Royal Sea-Bathing Hospital a girl who had been operated on in two different London hospitals and who on one side showed a long scar in front of the muscle and no less than three parallel ones behind. The other side had two crescentic scars, evidently the site of a fairly large operation, from beneath one of which incisions I have removed a considerable quantity of deep caseous glands.

---

[22] I regret that at the time of writing the above I had not noticed [illegible] was done by the late Dr. J. W. [illegible] ne particles and which is reproduced [illegible] LANCET, Dec. 6th, 1902, p. 1528).

When sinuses exist their orifices should be where possible included between elliptical incisions so as to make a transverse scar. Any damaged skin in connexion with superficial abscesses should be removed with a free hand, when it will in nearly all cases be possible to sew up the wound after the operation has been completed. In most cases when there is a superficial abscess projecting out from the neck the deeper glands will be found to be enlarged and suppurating and their free removal will allow a much more liberal excision of the damaged skin than would otherwise be the case.

Whatever incision be adopted, as every writer on this subject has insisted, attention must be paid to two very important structures, the internal jugular vein and the spinal accessory nerve, neither of which, and most assuredly not the latter, should be interfered with. At one time my impression was that the removal of glands *en masse*, rather than individually, increased the danger that these structures run, but a more extended experience has convinced me that such is not the case and in my later cases I have always endeavoured to extract the diseased structures with their capsules intact and as far as possible in one mass or chain. Taking the more common cases, those in which the enlarged glands are situated in the anterior and posterior triangles, their exposure is effected by the transverse incision I have already mentioned, the edges of skin and superficial fascia are freed for about an inch throughout the whole length of the cut, the anterior edge of the sterno-mastoid is defined, and the deep cervical fascia between it and the front of the neck is freely divided. This facilitates the exposure of the glands and allows the muscle to be retracted easily; the often large communicating facial vein is generally easily seen and avoided or ligatured if necessary. The muscle is freed for some distance above and below the margins of the incision from the glands beneath and then they themselves can be dealt with. The mass is seized and pulled up and its lower end defined; when separation from the underlying structures is begun the carotid sheath with the bulging internal jugular vein at once comes well into view and with that in sight there is no necessity to divide it. Even in very old cases where the masses were of enormous size and the adhesions particularly dense and fibrous the capsule of the glands has peeled readily enough off the vein. There is fortunately a fairly thick layer of fascia constituting the carotid sheath between the glands and the vein and it is to this intervening layer of fascia rather than to the thin-walled vein that adhesions are usually seen. Personally I have found after getting the glands raised at the lower end that separation of the mass from the sheath is best effected by the point of a sharp scalpel; the vein is more likely to be torn by a so-called blunt dissector applied with even slight force than injured by the point of a knife carefully used on the under surface of the glands. My experience is that once the mass is freed from the place where it is usually adherent to the sheath—that is, at its lower end—it is quite possible to peel it upwards. Although the ligature of the vein apparently makes no difference—in two of my earlier cases it was torn and had to be tied and Mr W. Watson Cheyne[1] recommends it as almost a routine procedure—the deliberate obliteration of such a large vessel should, I think, be avoided as it is possible to clear out the triangles very effectually and still to leave the vein intact. Further, it is permissible to doubt with Mr. W. H. A. Jacobson[2] whether the effect of the ligature on both sides of the neck on the cranial circulation is altogether harmless. I also question whether it adds in any way either to the rapidity or the ease with which the operation is performed, as the vein itself requires a ligature at both ends and so do as a rule four or five of its tributaries, including the facial, lingual, and superior thyroid; and in old cases with sinuses the risks of complications of a septic nature are obviously greater. As a rule the whole of the glands of the anterior triangle and those under the sterno-mastoid as far as the spinal accessory nerve can be removed through this transverse incision after separating them from their connexions and working entirely from the front of the muscle. In the larger cases I generally find that the chains of glands are practically divided into two by the spinal accessory nerve which in the posterior triangle crosses the lower part of the space in a kind of sulcus in the mass, and it is as well on reaching its vicinity in the upper part of the anterior triangle to have the muscle well retracted, when the nerve can be brought into view, as it is liable to be cut in separating the glands from the fascia on the under surface of the sterno-mastoid just where the nerve enters it, and is also in danger as it lies over the transverse process of the axis on its oblique course backwards into the muscle. For here a fairly constantly enlarged group of glands is to be found beneath a tough fascial covering between the axis and the mastoid process, and as the dissection is necessarily carried on at a considerable depth the muscle should be pulled well backwards and the nerve identified and avoided. Where there is a fairly large mass in the upper end of the posterior triangle, after loosening most of the glands from the front, and particularly after clearing the vein and the spinal accessory nerve, a vertical incision should be made along the back of the muscle, its edge should be defined and lifted from the glands beneath, and their removal is then proceeded with by working from behind forwards until the connexions with the anterior group are reached. The posterior set of glands will also have to be separated from the carotid sheath and this procedure is very much facilitated by the previous exposure and definition of the vein through the anterior wound. Even if the glands pass, as they occasionally but only rarely do, beneath the vein, they are readily separated from it as the vein itself can be retracted, when by pulling on the already loosened group of glands the deeper ones can be released with a few touches of the knife. It is seldom requisite to divide the sterno-mastoid as the muscle can be lifted up quite sufficiently for all practical purposes. If the submaxillary glands are enlarged their removal is a very simple matter and they are best cleared out of the way first. The branch of the facial nerve to the lower lip can hardly escape division and the facial vein has often to be divided between ligatures, but the labial paralysis as a rule improves in a few months and the division of the vein is of not much importance.

It is well in the larger cases to remove the glands in two or more groups so as to insure the definition of the spinal accessory nerve in the posterior triangle, and in perhaps most cases it may be easier to clear the anterior group out of the way rather than to bring them all out with the posterior ones. Again, in the larger cases, in working in the lower part of the area under the sterno-mastoid where a chain of glands, usually separate from the upper groups, often extends below the clavicle in close contact with the jugular, vertebral, and innominate veins the glands should be pulled well out behind the muscle and separated from the carotid sheath, brought well into view by having the sterno-mastoid drawn firmly forwards. Once the process of separation is started by dividing the fascial attachments to the sheath their removal is effected with little risk. In this situation a blunt dissector is a highly dangerous instrument as the large veins in this region are put on the stretch and would tear easily. The glands should be pulled well into actual sight and their excision should be carried out by light touches with the point of the scalpel directly on to the capsule of the gland. It is well not to pull glands out from under the sternum and the clavicle unless their attachments can be brought up with them and the position of the thoracic duct on the left side should be remembered before attempting the removal of deep and adherent glands in this highly dangerous situation. If in addition the subclavian glands are enlarged their removal is best effected at a subsequent operation. Access to the glands is obtained by a transverse cut across the space, about an inch above the clavicle, and the superficial veins having been tied and divided the space is cleared from above downwards. Here the capsules of old glands are often adherent to the pleura and here, as a rule, it is better not to attempt to remove the capsule but to incise it and to shell out the glands. This region is perhaps the least satisfactory in the neck; the glands are often very adherent, frequently several veins require ligature, and it is most difficult to apply pressure with any comfort to the patient when the dressings are applied. Where both subclavian and axillary sets require excision the question of dealing with both at the same operation is always considered, but if the case be at all a large one, and especially if it be complicated by sinuses or scars of previous operations, the operator will perhaps best serve the interests of his patient by deferring the axillary region till the subclavian has healed. When the glands are removed in this way with as much of the cellular tissue as is possible with them, the resulting wound should show a complete dissection of the anterior and posterior triangles, and unless the carotid sheath with its branching vessels in front and the muscular wall of the posterior triangle behind are seen quite clearly it is impossible to say with certainty that a goodly portion of the capsules of the glands, and not improbably many of the glands themselves, have not been left behind to give trouble at a later date. Where sinuses have been present or where broken-down glands have burst in the wound I have been in the habit of flushing out the entire area with a 1 in 1000 solution of biniodide of mercury and so far have had no cases of sepsis. All hæmorrhage is, of course, carefully arrested, the bleeding points are tied with fine silk, and the wounds are sewn up with the finest gossamer gut, a large number of stitches being inserted and pressure kept up by a very copious dressing. It is well to remove the stitches not later than the fourth day as otherwise the stitch marks will show, and to insure healing of the deeper parts of the wound it is well to keep the patient lying down for from ten to 14 days at least.

---

[1] Surgical Treatment, part 6, p. 148.

[2] Operations of Surgery, fourth edition, p. 560.

I have certainly seen good results follow in Margate from the more partial operations, such as incising and curetting a superficial abscess and scraping out the underlying glands, or the dissection of the greater part of the glands off the sheath and scraping the rest, but the after-treatment of these cases included prolonged rest and the best of open-air treatment and food. Such conditions are only obtainable when the patients are well-to-do and can give time and attention to the treatment, whereas with a more complete operation—and I have treated nearly 100 cases of various sizes in this manner—healing is as a rule rapid and permanent and the thickened masses under the scar that are often seen after a partially cleared case appears to have soundly healed scarcely ever occur. Recurrences of glandular enlargements certainly may, and often do, take place if the general health of the patient be not maintained by keeping him in a proper atmosphere and surroundings, but at all events recurrence in the same place is practically impossible as all glands and infected cellular tissue have been removed from the operated area.

The rapid improvement in the general health of the patients after these operations is quite remarkable in spite of the frequently difficult and tedious dissections incurred in clearing the diseased areas; such improvement is no doubt accelerated by the system at the Royal Sea-Bathing Hospital of putting the patients in the open air and practically on the sea front almost on the day after the operation, as my recollection of such cases in London and a large provincial hospital is by no means so favourable. Here in Margate the results of clearance in cases where large masses are much broken down and where the contents of the capsules are of a cheesy, semi-fluid consistence are almost always satisfactory, the patient's strength is quickly built up, and if the other side or the axillæ have to be dealt with a week is usually a sufficiently long interval. If both sides are affected and the glands are not excessively large I usually clear them out at the same operation, but considering the often feeble condition of the patients it is hardly wise to subject them to an anæsthesia for more than 90 minutes at a time and this limit is often exceeded for one side, though possibly operators of greater experience would look on this as an extremely liberal estimate. I have had cases this year where four and five operations have been performed on the same patient, a different area being cleared at each sitting; in one case in particular, that of a young adult female who had already had a foot amputated as a child for tuberculous disease, both sides of the neck and both axillæ were cleared in three weeks. Both sides of the neck were treated by throwing a flap forwards as already described and the triangles were completely cleared. The scars of the operation are scarcely visible at all from the front and the improvement in the patient's appearance and general condition when she left the hospital a few weeks after the operations was enormous.

Some months back my attention was directed to a communication in the *British Medical Journal* quoting four or five cases of meningitis occurring in patients after removal of tuberculous glands. I have only seen one case of this condition occur after operation on the glands and I have been present at several hundreds. I have seen several cases occur at the hospital here in spine and joint cases and have seen one man develop it a month or so after amputation for disease of the knee-joint. The one case in my recollection associated with glands was in a very unhealthy child with large masses of broken-down glands in both sides of the neck and both axillæ. The child was kept in the open air and fed up for several weeks in the hope that some improvement would take place, but as she was steadily getting worse it was decided to clear out the worst of the glands. One axilla was accordingly operated on, this being followed a week later by an operation on the posterior triangle through the scar of an old incision and a large number of broken-down glands were removed. In the course of doing this a large abnormal vein was cut and had to be tied but as the condition of the patient became critical under the anæsthetic the operation was not satisfactorily completed. The wound in the neck did not heal and in a month from the operation definite signs of meningitis showed themselves. The patient was taken home soon after and I have not been able to trace her. It is absurd to attempt to argue from one case and especially one in which there was such extensive disease, but it would appear to the ordinary mind that tuberculous infection of the meninges is more likely to follow an incomplete operation such as curetting and leaving the infected capsules in the wound than one in which nearly every particle of diseased tissue is taken away. It is also just as likely that tubercle bacilli can be conveyed to the meninges as the result of the glands bursting into the cellular tissue of the neck when left to themselves, so that the occasional occurrence of tuberculous meningitis in connexion with glands becomes an additional argument for a radical and complete operation.

The conclusions to which my present experience in the operative treatment of glands of the neck has led me are that if an operation is decided on the glands should in all cases be removed with their surrounding cellular tissue and that the internal jugular vein so far from being divided and tied as a routine procedure can almost always be avoided. The drooping of the shoulder caused by the division of the spinal accessory nerve is a very real deformity, causes considerable loss of power, and if the patient is a child is a source of almost certain lateral curvature. I have seen many old cases where both the sterno-mastoid and the trapezius have atrophied and their appearance, with the longitudinal scars extending from the mastoid to the clavicle, has been a sufficient object-lesson, not only to try to treat the nerve with the greatest respect, but to put the incisions in the least visible region.

Margate.

THE SUCCESSFUL TREATMENT OF A FEW CASES OF LUPUS.

BY C. STANSER BOWKER, L.R.C.P., L.R.C.S. EDIN., &c.,
LATE RESIDENT SURGEON AT THE GLASGOW ROYAL INFIRMARY, NEWPORT AND MONMOUTHSHIRE HOSPITAL, AND ROTHERHAM HOSPITAL AND DISPENSARY, ETC.

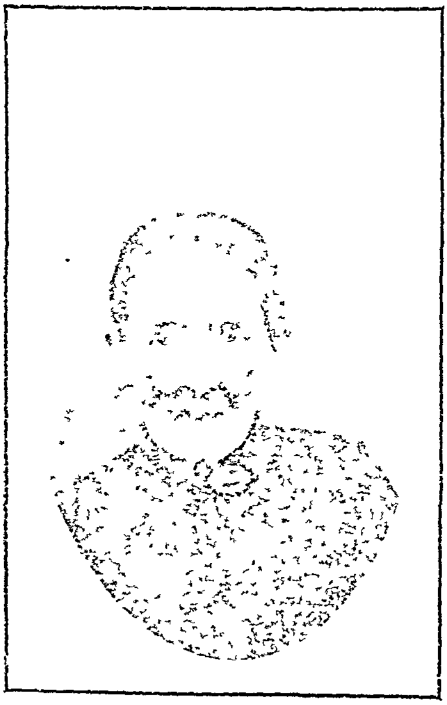
LUPUS may be regarded as one of the most disfiguring as well as one of the most formidable diseases which a medical man is called upon to treat, and from the fact that it is classed amongst the incurable diseases has not received sufficient attention to stay its progress and transgressions or arrest its evil results. Whatever treatment is adopted the progress is slow and requires patience and perseverance both on the part of the patient and of the medical man.

The following seven cases which I have taken from my note-book extend back a period of thirteen years and in all the cases that I have had occasion to treat very satisfactory results have been achieved in those cases where the disease has not been in a very advanced condition.

CASE 1.—The patient, a married woman, aged 42 years, had suffered from lupus for six years previously to the time that she came under my care, which was in March, 1890. The disease at this time had extended as high as the nasal bones and involved the whole portion of the nose below this point, attacking the mucous membrane of both nares, and there were various scattered foci on either cheek. Indirectly the disease affected both eyes which were more or less inflamed and watery and the sense of smell and of taste was practically gone. The treatment I adopted was the removal of the diseased tissue by excision as far as was possible, injections of Koch's lymph alternated with the injection of arsenic in the form of Fowler's solution, and wherever a suspicious-looking spot occurred it was immediately excised and the resulting wound was painted or dressed with a mixture of carbolic acid and guaiacol. The first injection of lymph produced a reaction of 101° F. and in all the patient received about 80 injections of lymph and arsenic, the highest reaction being 103°. This patient was under treatment for six months, at the end of which time I dismissed her as being quite well and she has remained so up to the present time, there being no sign of recurrence. I may mention that in this case the wounds had been scraped and burnt a considerable number of times but without any permanent good result.

CASE 2—A boy, aged 14 years, came to me in 1890 with a considerable lupoid patch, about one and a half inches square, situated over the first metacarpal bone of the right hand. The boy was an all-round delicate subject and his parents informed me that the wound had been scraped and burnt at various intervals but to no purpose. The treatment adopted was similar to that in the previous case. The whole of the diseased tissue was excised and the wound was dressed every day with the solution of guaiacol and carbolic acid. The injections of the lymph and arsenic produced very considerable disturbance, the highest temperature reached being 104·3° F. This boy was under treatment for three months and improved very considerably from the time that the lupoid patch was removed and the injections were commenced. He was dismissed at the end of three months perfectly well, the wound being quite healed, and his general health having much improved. There has been no recurrence of the disease since.

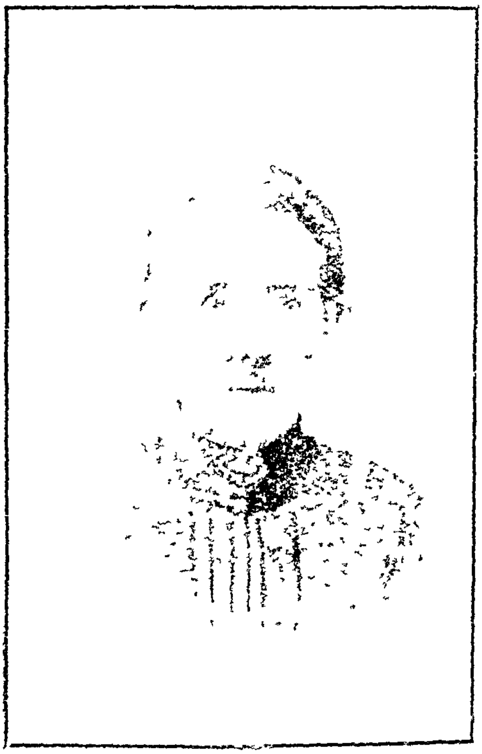
FIG. 1.



Condition of patient before treatment

CASE 3—A married woman, aged about 40 years, came o me in June, 1891, with lupus affecting the nose, the cheeks, and the entire surface of the upper lip. In this case a strong solution of cocaine was applied to the sores after the scabs had been removed until complete anæsthesia was produced; a small scalpel was taken and the disease was completely excised. A portion of both alæ was removed as the disease had penetrated most deeply at these places and the face was dressed with the same solution as in the previous cases. After excision the patient was injected continuously for about four months, no reaction being produced at the end of this time, and the highest temperature produced was 103° F. I may mention that after excision of the disease which covered a large portion of the face a very considerable wound remained, and as soon as healthy granulation tissue sprang up innumerable small skin grafts were dotted over the surface which gradually spread and coalesced. The patient was dismissed after four and a half months' treatment. Herewith are appended reproductions of photographs showing the condition of the face before and after treatment (see Figs. 1 and 2).

FIG. 2.



Condition of patient after treatment.

CASE 4—The patient, a man, aged 60 years, came under treatment in 1893 for lupus affecting and limited to the nose Incision of the whole of the disease was easily done in this case and the injections of lymph and Fowler's solution were persevered in until no reaction took place and the patient was dismissed after two and a half months with the nose perfectly healed.

CASE 5.—The patient, a married woman, came under treatment in 1893 with the disease affecting the inner canthus of the left eye, extending on to the nose and implicating a small portion of the lower lid. In this case, as in the previous cases, everything had been done in the way of scraping and burning to stay the progress and to rid the patient of this much dreaded malady but to no purpose, the disease slowly but surely extending. Thorough excision was performed, keeping well clear of suspected diseased tissue, and the resulting wound was dressed with guaiacol alone Injections of the lymph and arsenic were given as before mentioned until there was no reaction and the patient was given a clean bill of health at the end of two months. The result has been of a permanent nature up to the present time.

CASE 6.—A man, aged about 40 years, came to me in 1895 suffering from a very considerable lupoid sore situated about two inches below the mastoid process and immediately over the sterno mastoid muscle. The patient stated that this ulcer had been gradually extending for some years past, although he had had it cauterised and scraped on innumerable occasions, but it had never shown any tendency to heal. Excision was performed, keeping well beneath the base of the ulcer and well outside the margin of the disease. A few suspicious-looking spots situate around the main ulcer were also excised and the resulting wound was dressed every day with the guaiacol and carbolic solution. A week after the excision healthy granulation tissue made its appearance and before the termination of the injections of the lymph and arsenic the neck was perfectly and solidly healed. The patient has had no recurrence, having enjoyed very good health since.

CASE 7.—This case is interesting, since the disease was rather advanced, affecting the whole of the lower half of the nose, extending to both alæ nasi and involving in scattered patches both cheeks, attacking the lower lip, mucous membrane of both nares, and the skin covering the inferior border of the septum nasi, but not involving the septum. Complete excision of the lower portion of the nose was done, including the alæ nasi, the inferior border of the septum was skinned, and practically the whole of the diseased tissue was removed. After the operation the injections were commenced in very minute doses, as I discovered some cardiac valvular mischief which I decided might be tuberculous; there was also a suspicious spot in one eye which became very much inflamed under the influence of the injections but this inflammation ultimately disappeared. This patient had entirely lost the power of smell and the sense of taste was practically gone. A short time, however, after the removal of the diseased portion of the nose and after a few injections both smell and taste returned. *The highest reaction of the lymph took place* after the twelfth injection, the temperature reaching 104° F. and producing very considerable disturbance of the system in the shape of severe headache, pains in the legs, and a stiffness about the neck with vomiting of a yellowish material streaked with blood, and a very dry tongue, together with considerable disturbance of the circulatory system. However, this condition soon passed away and the injections were continued. The wound resulting from the excision rapidly healed and there was a decided improvement in the general health of the patient. This case having undergone treatment recently and the disease apparently being extirpated it was decided to wait for a few months to see whether any recurrence would take place and if not to perform a plastic operation in order to give the nose a better appearance, although the disfigurement is not at the present time objectionable. Suffice it to say that although the disease was extensive the treatment has, up to the time of writing, produced a very beneficial and satisfactory result.

It will be seen from the above cases that the main treatment consists in the injection of Koch's lymph and arse[illegible] combined with the thorough extirpation of the dis[illegible] *tissue, and the local* treatment must be adapted and [illegible]ed to suit individual cases. If the wound left after exc[illegible] be extensive small skin grafts will be found of great service in hastening the healing process; and I have had occasion in several cases to do plastic operations in order to restore the nose to something like its original shape and in the cases where this has been necessary the result has been fairly successful and with every satisfaction to the patient. The cases above quoted had all been treated previously by the method of scraping or burning and there was no doubt as to the diagnosis.

Newport, Mon.

A NOVEL SMALL-POX WARD.—At the meeting of the Calne (Wiltshire) district council held on Oct. 26th, the clerk was instructed to make inquiries as to the cost of a disused railway carriage which is to be utilised for the reception of small-pox cases should an outbreak occur.

ROYAL ALBERT HOSPITAL, DEVONPORT. — A public meeting of the inhabitants of Stonehouse was held at the town-hall on Nov. 5th to take steps to obtain increased support from Stonehouse for the Royal Albert Hospital. The Earl of Mount Edgcumbe, Viscount Clifden, Lord St. Levan, and several others were present. It was eventually decided to elect a committee of working men for the purpose of collecting subscriptions and also that an appeal should be made to the private residents and tradesmen of Stonehouse. It was also agreed that the ladies of the district should be invited to assist the institution.

ON SUPPURATION OF THE BURSA OVER THE TROCHANTER MAJOR AND ITS OCCASIONAL IMITATION OF HIP DISEASE.[1]

BY T. PRIDGIN TEALE, M.A. OXON., F.R.C.S. ENG., F.R.S.,
CONSULTING SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

IN THE LANCET of Oct. 8th, 1870 (p. 506), I published an essay on this subject, the opening paragraph of which I will quote.

> [illegible] bursa [illegible] between the trochanter major and the flat tendon of the gluteus maximus which is inserted into the fascia lata. Although the affection cannot be of very rare occurrence, and must be known to many surgeons, I cannot find any definite mention of it either in general works on surgery or in special works on joints and not even a hint as to the importance of appreciating it in the diagnosis of hip disease. The nearest approach which I can find is a notice of caries of the trochanter major, which I suspect may at times originate in the disease in question.

This was written 33 years ago. My attention to the subject has been drawn to it anew by a case recently under my care in the Leeds Infirmary and by a letter from an old house surgeon, Mr. F. W. Storry of Stroud, stating his recollection of a clinical lec[illegible] asking where he could meet [illegible] could not find mention of it i[illegible] Moreover, I have failed to find any adequate appreciation of the question in recent works. The case recently under my care possesses a special point of interest in the occurrence of a plate of bone in a septum separating the main bursa under the flat tendon of the gluteus from a secondary bursa over the trochanter and seems to afford a suitable pretext for reviving the points of diagnosis and practice laid down in the original essay of 1870.

A man, aged 51 years, a patient under the care of Mr. F. Laird of Ravensthorpe, was admitted into the Leeds Infirmary on June 22nd last *with two discharging sinuses, one* behind the trochanter, the other just below the buttock leading to a suppurating cavity extending about three inches down the back of the thigh. There were also two scars of old sinuses in front of the upper part of the femur. Though slightly lame he could walk with tolerable comfort and except for the situation of the scars and sinuses there was nothing to suggest hip disease. There was little impairment of the mobility of the joint. In this respect it differed from my first case and some others in which the femur was rigidly fixed until the muscles were relaxed under an anæsthetic, when all rigidity disappeared and the movements of the femur became smooth and almost unrestricted. The patient gave the following history. When about 14 years of age he was kicked in the region of the trochanter. He had pain for about an hour and then went on with his work. 16 years later a lump of about the size of a walnut appeared at a point about one and a half inches below the trochanter. A year later this lump was opened by Dr. A. Anderson of Mirfield, and as far as the patient recollects clear fluid was let out. After discharging for three years the sinus healed. Fifteen years later—i.e., four or five years ago—the sinus opened out again and continued discharging until his admittance under my care. *Three years ago a second sinus in front of the* trochanter was formed and nine months ago a third sinus below the buttock opened and was discharging pus freely on his admission. The opinion formed by the resident surgical officer and my house surgeon was that the hip was sound but that the source of the trouble was necrosis of the upper part of the femur. I suggested the probability that the case was one of diseased trochanteric bursa.

Having enlarged the sinus behind the trochanter so as to introduce the finger the interior of the bursa was reached, the floor of which was rough as if from a carious surface of the trochanter. The next step was to lay open the bursa by direct incision, dividing the gluteal aponeurosis so as to expose to touch and view the rough bony surface. This surface, to my surprise, was loose, gliding over the trochanter, and it proved to be a bony plate of about the size of a shilling in the septum between the great bursa and a small subsidiary bursa in contact with the trochanter There was no trace of any other diseased bone but a healthy fixed plate of bone could be felt extending deeply behind the trochanter. The bursal plate was excised, leaving a perfectly smooth synovial surface of the trochanter, and the division of the gluteal tendon was completed. The sinus below the buttock was enlarged and was found not to communicate with the bursa above. A counter opening for drainage was made at the lower part of the suppurating cavity. The patient returned home on the twenty-fourth day. When he called on me in the last week of September he was walking with perfect comfort and the sinuses were all but healed.

---

[1] A paper read at the meeting of the Leeds and West Riding Medico-Chirurgical Society on Oct. 23rd, 1903.

Not long after the publication of my essay in 1870 I had an interesting letter from Dr. R. Macnab of Bury St. Edmunds, now residing at Tobermory in Argyllshire, in reference to two cases evidently of the same character which he published in November of the same year in THE LANCET.[2] In one of these he maintained, in opposition to the very strongly expressed opinion of his colleagues, that the case was not hip disease, but trochanteric abscess. Fortunately, he held to his opinion. He opened the abscess freely and, as he believes, in doing so freely divided the gluteal tendon and the patient made a very rapid recovery. It may be that the affection is a rare one, as I do not remember to have seen more than two or three besides these related either in the practice of my colleagues or myself.

In further illustration of the subject I recall an instance of a girl who, having fallen heavily on the trochanter, came to the infirmary two or three weeks after the fall with a swelling in the situation of the bursa and consequent lameness. I divided the gluteal aponeurosis subcutaneously and she very rapidly recovered. This I relate from memory.

The points I would lay stress upon are these: (1) a *prima facie* suspicion of hip disease; (2) either no marked muscular rigidity and fixity of the hip-joint or, where such exist, their disappearance under an anæsthetic; (3) the absence of tenderness on pressure of the head of the femur against the acetabulum; (4) the frequency of the history of a fall on the trochanter; and (5) the effect of the flat tendon of the gluteus maximus as a factor in keeping up the diseased condition of the bursa and the importance of the division of this tendon in the surgical treatment of the disease.

In the work by Rose and Carless disease of this bursa is referred to as "not uncommonly the seat of tuberculous disease" and that "it somewhat resembles the earlier stages of hip disease." "Treatment consists of incision, scraping, and disinfecting the interior and allowing it to heal from the bottom."

The points which need to be enforced by teachers are: (1) the importance in many cases of a traumatic and non-tuberculous origin; (2) the fact that simulation of hip disease is at times so close that experienced surgeons may on first seeing the case be misled and even after mature consideration be mistaken; and (3) that above all things the division of the flat tendon of the gluteus is a dominant factor in promoting rapid cure.

Leeds.

PS.—Mr. Laird reports to me that his patient now goes about with more comfort than he has done for 30 years.

A GROUP OF CANCER CASES.

BY W. GIFFORD NASH, F.R.C.S. ENG.,

SURGEON TO THE BEDFORD COUNTY HOSPITAL.

WHILST collecting information as to the incidence of cancer in North Bedfordshire for the decennial period 1890-99 I came upon a group of three cases of cancer of the tongue in the same village in which the patients all died within a period of 16 days. As cancer of the tongue is a comparatively rare disease, only 20 cases occurring in a population of over 102,000 in ten years, I was induced to make further inquiries into these three cases and into two others which appeared to be associated with them. This series of cases is so interesting that I think it best to make it known. Early this year Mr. Kilham Roberts, medical officer of health of the Ampthill rural district, kindly made inquiries into the five cases, four of which, including the three cases of cancer of the tongue, occurred in one village and the other, marked A below, in an adjacent village.

CASE 1.—A, a man, aged 67 years, died from cancer of the rectum on May 22nd, 1892.

CASE 2.—B, a man, aged 79 years, died from cancer of the tongue on June 4th, 1893.

CASE 3.—C, a man, aged 69 years, died from cancer of the tongue on June 11th, 1893

CASE 4.—D, a man, aged 67 years, died from cancer of the tongue on June 20th, 1893.

CASE 5.—E, a man, aged 43 years, died from cancer of the lip on Oct. 18th, 1893.

The patient A was brother-in-law to the patient D. I cannot do better than give the results of Mr. Roberts's inquiries in his own words, substituting, however, for the names of the patients the first five letters of the alphabet respectively as in the foregoing.

"First I will take the cases of C and D. The widow of C, who was an innkeeper, informs me that D and her husband were great friends and that they *frequently drank together out of a large tankard;* in fact, before their illnesses they used to meet two or three times a week. D seems to have contracted the disease first and on more than one occasion when drinking he complained of soreness under the tongue. The widow of C says that she always believed her husband caught it from D although I did not suggest any connexion. B was no friend of the men previously mentioned but occasionally as he passed through the village he stopped at the inn kept by C to have a drink and C's widow is certain that her husband and D never drank with B, but it is possible that the last mentioned drank out of a vessel which C and D had previously used. The cleansing which drinking-vessels get at the majority of village inns is not sufficient to destroy the infectivity of any disease. E lived in the same hamlet as B and came little in contact with C and D. He, however, frequented the same inn as B but did not drink out of the same vessel. Soon after his illness started he used to take his own glass to the tavern.

"I now come to what I consider the most interesting portion of the narrative. C's widow informs me that A was a bosom friend of D and also of her husband. They frequently drank together out of the same vessel both at C's inn and at each other's houses."

Bedford.

A CASE OF LUPUS OF THE FOREHEAD, THE RIGHT ARM, AND THE ELBOW TREATED BY EXCISION.

BY CECIL H. LEAF, M.A., M.B. CANTAB., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE CANCER HOSPITAL, BROMPTON, AND TO THE GORDON HOSPITAL FOR RECTAL DISEASES.

THE following are brief notes of this case.

The patient, aged 36 years, unmarried, came to [illegible] patient department of the Cancer Hospital, Brom[illegible] Oct. 15th, 1902. She was found to have a patch of lupus of about the size of a shilling which was situated above, and to the outer side of, the left eyebrow (Fig. 1). There was another patch, two and a half inches in the vertical and two inches in the transverse diameter, on the outer side of the right arm. The upper part of this was situated at about the junction of the upper and middle third of the arm. Over the front of the right elbow was a still larger patch, measuring about three inches in the transverse and two inches in the vertical diameter (Fig. 3). Treatment with a 5 per cent. solution of formalin, which I ordered to be painted on every third day, and subsequently once a fortnight, at first caused a marked improvement. However, it soon became clear that it would be useless to hope for a permanent cure from this method. I therefore admitted the patient into the hospital with a view of excising the patches. This I did, the patches on the forehead and arm being excised on April 3rd, and that on the elbow on April 17th. The latter operation left a large, raw area which was subsequently grafted by Thiersch's method on the 24th. There was a slight amount of tension in bringing the edges of the wound on the forehead together, but, as Fig. 2 shows, there *is no* disfigurement left except a trifling pulling upwards of the

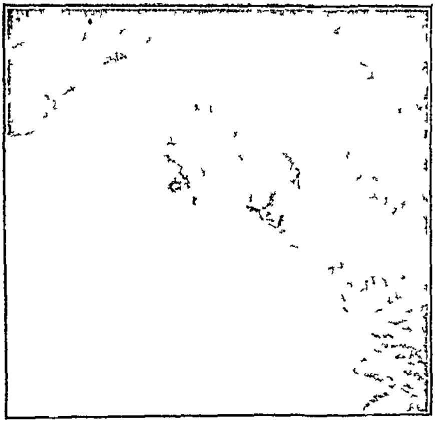
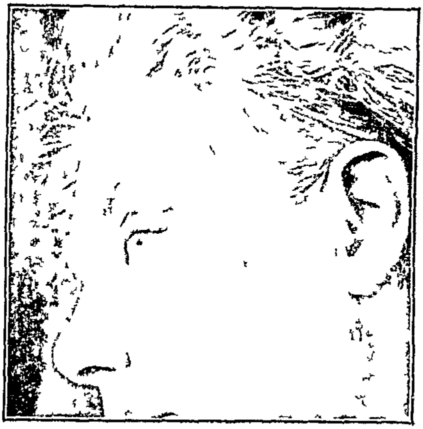
FIG 1



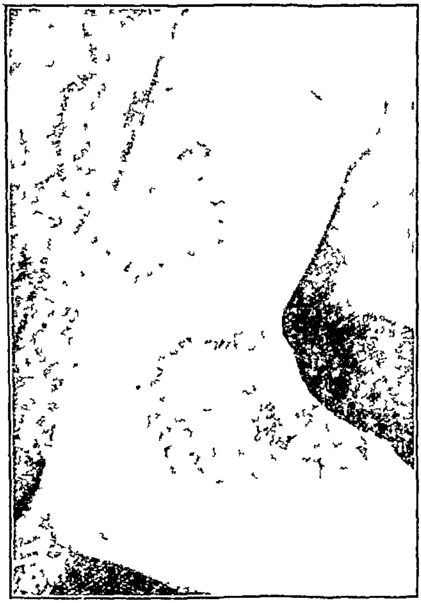
Condition of the patient's face before operation

FIG 2



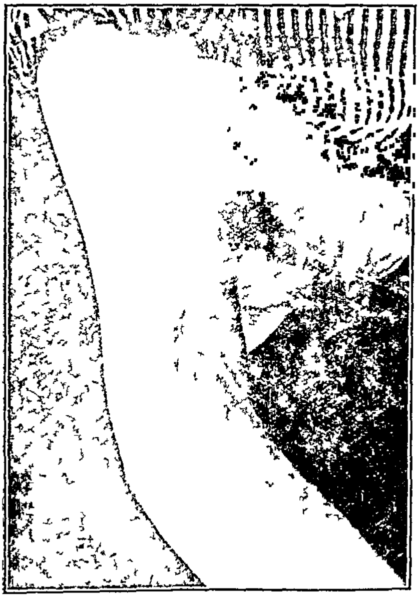
Condition of the patient's face after operation

FIG 3



Condition of the patient's arm before operation

FIG 4



Condition of the patient's arm after operation between the gums, the patient having previously had her artificial teeth removed. On the 20th and 21st ten cubic centimetres of antitetanic serum were injected on each day, the patient's condition improving after each injection. In all, nine injections of ten cubic centimetres were given. From this time her recovery was uninterrupted, with the exception of the adductors of the thigh, which remained in a state of tonic spasm for several days after the other muscles had become quiescent.

This case is of interest for several reasons. First, the apparent rapid onset of tetanus, within 36 hours after the injury, and then the disappearance of the symptoms; secondly, after the excitement of seeing friends, the sudden reappearance of tetanus on the ninth day; and thirdly, how the spasms yielded to the antitetanic serum and how on Sept. 15th when no injection was given the spasms were very severe. I may say that this is the only case of tetanus in which I have had an opportunity of using the serum. The few other cases which I have attended previously to the introduction of the serum all terminated fatally.

Amhurst-park, Stamford-hill, N.

A CASE OF CHONDROMA ATTACHED TO THE SUBMAXILLARY SALIVARY GLAND.

By H. J. ILOTT, M.D. ABERD., M.R.C.S. ENG.,
MEDICAL OFFICER, BROMLEY (KENT) COTTAGE HOSPITAL.

A TALL, rather anæmic girl, 16 years of age, was admitted into Bromley (Kent) Cottage Hospital on July 28th. She had a hard, moveable, nodular growth in the right submaxillary region. It had been slowly developing for the past seven or eight years. It was then of about the size of a large walnut. The growth was removed by me on August 4th. It was situated beneath the deep fascia, was encapsuled, and by its base was adherent to the submaxillary salivary gland. On section the growth was firm and white, with a few small yellowish-brown patches of somewhat softer consistence. It was sent to the Clinical Research Association for examination and Mr. J. H. Targett reported as follows: "This tumour is a chondroma of the submaxillary salivary gland. It is well encapsuled and shows no signs of malignancy. There is much imperfect gland-tissue mixed with the cartilage. It is now usually regarded as an endothelioma." The wound healed quickly and the patient was discharged on August 13th. These growths have been noticed as occurring in connexion with the parotid glands, but as they are rare and I have never heard of one in connexion with the submaxillary gland I think the case is worth recording.

Bromley, Kent.

SEAMEN'S HOSPITAL, CARDIFF.—The new Seamen's Hospital at Cardiff is now approaching completion. The total cost will be about £35,000, towards which about £17,000 have been promised.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.—A meeting of the council of the association was held at 13, Hanover-square, W., on Nov. 9th, Sir William Broadbent being in the chair. Previously to holding the council meeting a preliminary meeting of the general committee for making arrangements for the Paris Congress in 1904 was held. At this meeting Sir William Broadbent was unanimously elected chairman of the general committee and Dr. J. J. Perkins honorary secretary. An executive committee was also formed, consisting of 12 names. It was decided to invite members of the staffs of the various hospitals for diseases of the chest to join the general committee, as well as several influential laymen who are interested in the subject of consumption. It was also resolved that the medical officers of health from the counties as well as from the chief towns should be invited. The secretary read a *précis* of the replies from the medical officers of health of the metropolitan boroughs with regard to spitting in public-houses. It was resolved that the matter should be postponed and that no further action should be taken for the present, as the whole subject was shortly to be considered by the Incorporated Society of Medical Officers of Health. The secretary reported that branches of the association had been formed at the Aberyswyth University and at Adelaide, South Australia.

NORWOOD COTTAGE HOSPITAL.

A CASE OF REMOVAL OF THE APPENDIX WITH CONCRETION; RECOVERY.

(Under the care of Dr. JOHN H. GALTON.)

A MAN, aged 23 years, was admitted into the Norwood Cottage Hospital on May 6th, 1903. The family history was good. In 1896 he had an attack of pain in the right iliac region and was in bed for six weeks. In 1898 he again had an acute attack and was then taken to St. Bartholomew's Hospital. On Dec. 15th he ate half a pound of raw chestnuts and on the 16th he was doubled up with severe pain which was accompanied by semi-collapse and cold sweats. His temperature was 99° F. and his pulse was 100 The abdomen was slightly full and rigid and did not move on inspiration; it was tender everywhere, especially over the right iliac fossa. There was rather more resistance at the right iliac fossa but nothing could be felt. The percussion note was resonant in both iliac fossæ. On the 18th he was seen by the surgeon who thought that there were no indications for immediate operation. On the 22nd in the right iliac fossa above Poupart's ligament there was a distinct swelling in the region of the appendix. On Jan. 11th, 1899, he was quite convalescent and was taken into a surgical ward for the purpose of examining the appendix, and on the 21st he was discharged without undergoing an operation. (These notes were copied by the patient from the bed card at St. Bartholomew's Hospital). After his discharge he went to Folkestone and while there had a slight return of pain. During the last three years he had had several attacks of pain in the same region but had never been laid up. On examination there was no dulness on percussion over the right iliac fossa, but two and a half inches above Poupart's ligament and parallel with it a line of hard tissue one inch long could be rolled under the finger which on examination at another time was found to be in a different position one inch away from the former, and just over the middle of Poupart's ligament was a small hard swelling of the size of a hazel nut.

On May 7th, at 11.30 A.M., chloroform was administered by Mr. A. Scott Turner by means of Junker's apparatus and Dr. C. E. Michael assisted at the operation. The abdomen was opened by an incision four inches long and two and a half inches above Poupart's ligament and the healthy omentum disclosed was found not to be adherent. A nodule of the size of the tip of the index finger pointing upwards represented the appendix which was thickened, one and a half inches long, and firmly adherent to the caput coli. The adhesions were divided with a sharp dissector and one ligature of sterilised silk was applied to a bleeding vessel The appendix was tied half an inch from the colon, the free end was touched with pure carbolic acid, and the peritoneal edges were brought together with a suture of sterilised silk. The appendix showed hypertrophied walls and a very hard stercolith one inch long, there being at the free end one and a half turns as of a corkscrew, as if the hypertrophied appendix had been trying hard to get rid of it. The abdominal wound was closed with four deep silver-wire sutures including the peritoneum and seven superficial horsehair ones and was dressed with sal alembroth gauze, cotton-wool, and spica bandage.

After the operation the pulse was 72 and good. On May 8th the pulse was 84 and the temperature was 98·4°. The patient complained of pain at the upper part of the abdomen. The progress continued to be good. On the 11th he was given half an ounce of castor oil at 3 P.M. and an enema of warm water at 8 P.M. On the 12th, no action of the bowels having taken place, white mixture was given every four hours. On the 14th the bowels acted. All deep sutures were removed. The wound had healed except half an inch in the middle. On the 15th the pulse was 80 and the temperature was 97·8°. The unhealed middle portion of the wound was discharging dirty pus. The suture wounds were angry-looking so hot boric acid fomentations were ordered. On the 17th the wound was looking quite healthy. On the 21st it had quite healed and was free from discharge and the scar was firm and sound. On June 3rd the patient was discharged cured.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Anæmias of Infancy.

A MEETING of this society was held on Nov. 11th, Mr. **ALFRED WILLETT**, the President, being in the chair.

Dr. **OLIVE RIVIERE** read a paper on the Anæmias of Infancy, which will be published in full in an early issue of THE LANCET. He adduced facts to show that anæmia of slight grade was common in infancy, but cases of more severe anæmia also presented themselves and were commonly described under the name "anæmia splenica infantum." These cases presented certain definite characteristics—enlarged spleen and liver, peculiar blood changes, nucleated red cells, a fairly large percentage of myelocytes, and often a leucocytosis. On account of these peculiar features such cases had been generally claimed as a distinct group, but it was probably more correct to suppose that they were in no way specific, but that all anæmias of infancy would show such changes if sufficiently severe, they being due to the peculiarities of the infantile blood and not to any specific causation.

Dr. **J. H. DRYSDALE** said that he, in conjunction with Dr. J. H. Thursfield, had during the past ten years examined the blood from cases of splenic anæmia in infants. Without controverting Dr. Riviere's facts he still could not agree that anæmia from any cause in infancy might give rise to "splenic anæmia." He thought that the primary disease must be of a severe type. He did not think that either rickets or congenital syphilis was the direct cause of the disease since both were common conditions while "splenic anæmia" was rare, though both these diseases were seen in conjunction with splenic anæmia and pseudo-leukæmia. He believed that the disease was due to some disturbance in the intestinal tract although gastro-intestinal catarrh was not present nearly so frequently in his own cases as in those quoted by Dr. Riviere. If the disease was due to this factor then careful feeding and diet should lead to rapid recovery which was not, however, the case. He then quoted two cases in which the blood examination presented an entirely different type from the cases quoted by Dr. Riviere, proving that all the anæmias could not be regarded merely as different stages of the same disease. It was important to remember, first, that the red cells and the white cells in the blood varied independently of one another, and that the diminution of the red cells might be of a slight degree, while the changes in the leucocytes might be very marked; and, secondly, that the changes which were found in blood in disease were symptomatic and not the disease itself. The clinical features of the disease were pallor, hæmorrhages, bleeding from the nose, the gums, and the rectum, and irregular rises of temperature. The duration of the disease was long, the average period in his series of cases being five and a half months. The spleen was enlarged and the liver was apparently enlarged (though after death on being weighed there was but little increase in weight). The superficial glands were not enlarged, whilst the mesenteric glands were enlarged. Treatment was usually unsuccessful whatever measures were tried. He thought that if rickets or improper feeding played any important part in the etiology then the cases should do well, but this was not so. The primary cause of the disease was still obscure.

Dr. **F. A. BAINBRIDGE** criticised the view advanced by Dr. Riviere that splenic anæmia and pernicious anæmia were both due to the absorption of toxin from the intestinal tract, in splenic anæmia the toxin passed into the blood stream, whereas in pernicious anæmia it was arrested in the liver. He pointed out that in splenic anæmia there was no free iron in the liver and also that in whatever portion of the body destruction of red cells took place the free iron was stored in the liver. He questioned whether there was any evidence for Dr. Riviere's statement that toxins absorbed from the intestine were excreted in the bile and so returned again to the intestine.

Mr. **L. S. DUDGEON** said that he considered the presence of the mast cells important in the diagnosis of a myelogenetic leukæmia, and that he had never seen an increase of mast cells in the blood of infants who appeared clinically to be cases of leukæmia. The blood had been of the chlorotic type with numerous nucleated red cells. The blood had been typical of a secondary anæmia. He had seen most of these cases improve under arsenic and mercury and considered that many were due either to congenital syphilis or to intestinal infection.

Dr. **S. VERE PEARSON** said that his experience with regard to the occurrence of hæmorrhage in splenic anæmia had been different from Dr. Riviere's for in four out of five of his cases there were epistaxis, purpura, and bleeding from ulcers on the scalp. He had seen twins both affected by the same disease. He thought that Dr. Riviere had not proved the connexion between the simple anæmia and the splenic anæmia, since he had shown no intermediate cases between the two conditions. He did not think that gastro intestinal disturbance was an important factor in the etiology of the disease, since such disturbances were common, while splenic anæmia was rare. He agreed with Dr. Riviere that there was no true leukæmia in infants.

Dr. **A. E. RUSSELL** quoted the case of an infant, aged 12 months, who had a greatly enlarged spleen. The blood count showed a very large number of nucleated red cells. The child rapidly improved under inunctions of mercury though there was but indefinite evidence of syphilis.

Dr. **E. P. BAUMANN** said that during the past two years he had had the opportunity of investigating cases of anæmia admitted to the Children's Hospital, Great Ormond-street. Many cases showed changes characteristic of secondary anæmia; these differed entirely from cases of splenic anæmia for from the beginning the blood changes were characteristic of this condition. The presence of myelocytes and nucleated red corpuscles was not the characteristic feature but he considered the polymorphous character of the blood to be of the most diagnostic value. In addition to the presence of abnormal cells, both finely granular and coarsely granular, there were polychromatophile degeneration and extreme poikilocytosis and marked variation in the size and shape of the red corpuscles. This polymorphous character of the blood he had never been able to demonstrate in the blood of secondary anæmia He had never been able to demonstrate the peculiar polymorphous change in cases of congenital syphilis although the blood had presented marked chlorotic characters, a diminished number of red corpuscles, poikilocytosis, nucleated red corpuscles, and some myelocytes being present. In every case of splenic anæmia examined the typical polymorphous character of the blood was present from the first and continued practically unchanged throughout the disease.

Dr. **RIVIERE** replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Nov. 9th, Dr. **F. DE HAVILLAND HALL**, the President, being in the chair.

Dr. **W. ESSEX WYNTER** exhibited a case of Addison's Disease occurring in a married woman, aged 40 years. Pigmentation had been noticed for two summers (about 15 months), during which time she had been growing weaker and had suffered from syncopal attacks. Wasting had been noticed for nine months. There were now general bronzing of the skin, intensified in the face, hands, and flexures of the joints, definite pigmentation of the mucous membrane of the mouth and tongue, and marked circulatory debility.

Dr. **WYNTER** also exhibited a case of Spondylitis Deformans ("poker-back").—The **PRESIDENT** remarked that the case differed somewhat from those which he had previously seen in which there had been more marked deformity of the spinal column.—Dr. **F. J. POYNTON** also agreed that there were generally much more thickening and distortion of the spinal column. One case which he had seen improved under massage and iodide of potassium.—Dr. **ALEXANDER MORISON** referred to a case in which there was a history of gonorrhœa.—Dr. **F. PARKES WEBER** thought that the case was a typical one of spondylitis deformans. Post mortem specimens generally exhibited bone formations in the vertebral ligaments.—Dr. WYNTER, in replying, said that the patient had been lying down for a long time and perhaps this explained the straightness of the back.

Dr. POYNTON showed a case of Bilateral Facial Paralysis occurring in a boy, aged five years, who was quite healthy until he had a fall downstairs in December, 1902 He was not unconscious or apparently much shaken by this fall. While in bed with the illness after the injury he developed difficulty in speaking and lost all expression in his face and could not close his eyes in sleep. There was now bilateral facial paralysis of an infranuclear type with evidence of some damage to the left auditory nerve. There were no symptoms pointing to diphtherial paralysis or to syphilis.

Dr. H. LEWIS JONES and Mr. C. S. KINGSTON exhibited three cases of Rodent Ulcer. Dr. Jones explained that they were shown for the purpose of eliciting opinions as to the best method of conducting x-ray treatment in such cases. There could no longer be any question of the efficacy of the treatment. The effect produced by the x rays could continue after suspension of treatment, as in the case of a man he referred to. Dr. Jones was inclined to think that the efficacy of the x rays in rodent ulcer was due to their special destructive effects on the sebaceous glands in which structures rodent ulcer started. X-ray dermatitis might be explained in the same way by the effects upon the sebaceous glands. The less effect in superficial epithelioma might be explained by the latter not starting in the sebaceous glands.—Mr. Kingston explained the method of the applications. It was remarkable that the resulting scar became quite level with the skin. The value of general as well as of local treatment was referred to. As regards superficial carcinoma x-ray treatment was also efficacious, especially in the relief of pain.

Mr. L. V. CARGILL exhibited a case of Rodent Ulcer treated by Radium Bromide. The patient, a man, aged 62 years, had had 21 applications of from 5 to 10 minutes' duration. The disease, which had existed seven years, had been operated on twice previously unsuccessfully. Radium was of value as needing no elaborate apparatus. The relative value of the x rays and radium had yet to be settled but there was no doubt as to the efficacy of the latter in this case.

Dr. S. E. DORE exhibited four cases of Lupus Vulgaris treated by the Finsen Light and the X Rays. The first case was that of a woman, aged 40 years, the disease being mixed with troublesome scar tissue and the 271 applications of the Finsen light had been very successful. The second case had been treated by x rays and the Finsen light combined. The third and fourth cases had been treated by the light only. All showed very satisfactory results. The value of successive and continuous applications of the Finsen light, especially to superficial nodules without allowing healing to take place between the sittings, and the usual absence of unsightly scarring afterwards were points in favour of the Finsen light. On the other hand, the x rays seemed advantageous when large areas and deep seated lesions had to be dealt with. Nevertheless, the x rays were liable to produce telangiectasis.

Dr. BERTRAND DAWSON exhibited an Abdominal Case for diagnosis in a man, aged 28 years, who had first noticed a lump in the right side of the abdomen three years before when he was serving in South Africa.—Mr. V. W. LOWE had seen the case previously and he thought the long history was against the diagnosis of sarcoma and suggested the possibility of hydatid tumour.—Dr. WYNTER, Dr. SEYMOUR TAYLOR, and Dr H. A CALEY concurred in the possibility of this view and Dr. DAWSON replied.

Dr. DAWSON also exhibited a case of Carcinoma of the Stomach.

Mr. W. G. SPENCER communicated a case of Scirrhus of the Tongue, which had been brought before the society for three consecutive years, showing the efficacy of treatment. The glands in the neck were becoming softer and were disappearing.

Dr. PARKES WEBER and Mr. R. LAKE exhibited a case of Epithelioma of the Lower Portion of the Pharynx in a woman, aged 31 years, who was affected with pulmonary tuberculosis. In June, 1901, she spat up some blood but the difficulty of swallowing had only come on six months ago. Microscopically the pharyngeal growth presented the typical structure of epithelioma.

Dr. C. S. DE SEGUNDO exhibited a woman, aged 25 years, who presented Swellings in the Subcrural Spaces which had developed in the last 12 months.—Mr. SPENCER suggested that these swellings might be chronic rheumatic thickenings of the synovial membrane, but Dr. DE SEGUNDO could not concur in this view, suggesting that they might be of tuberculous or syphilitic origin.

Dr. B. E. POTTER showed a case of Congenital Absence of the Right Hand in a male child, aged two years. The mother of the child mentioned that four months before his birth she had been much frightened by seeing a dog attack one of her children whose hand she thought was bitten.—Mr. SPENCER referred to a similar case in which he had found the remains of an amniotic band across the wrist.

OBSTETRICAL SOCIETY OF LONDON.

Acute Contagious Pemphigus in the Newly Born.—Ovarian Cyst.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 4th, Dr. EDWARD MALINS, the President, being in the chair.

Dr. GEORGE J. MAGUIRE read a paper on Acute Contagious Pemphigus in the Newly Born. Authorities were quoted to show that infantile pemphigus other than syphilitic, though known to occur, was rare, especially in this country. After stating the constitution of the charity in the practice of which the epidemic dealt with occurred, and after giving data as to the carrying on of the work up to the time of the outbreak of this epidemic, the period over which it extended was recorded, the number of deliveries during that period being 20, the number of infants affected with pemphigus being 18, and the number of deaths eight The clinical symptoms in the first case seen were described, followed by detailed notes of the history and symptoms in each case, with the result, and an abstract in tabular form was appended. It was concluded that the cases arose from a common contagion of septic origin (its source, however, being unknown) conveyed from case to case by a certain midwife, the probable method of conveyance being given. The contagiousness of the affection was proved and the number of cases infected from each infant was given. After quoting a paper by Bulloch in the *British Journal of Dermatology* in 1896, which contained an account of the micro-organisms found in previous epidemics of pemphigus neonatorum, there was given the result of the bacteriological examination of serum from two of the cases, the pathogenic germ isolated being the staphylococcus pyogenes aureus. The incubation period was then inquired into and an endeavour was made to fix the time required—(1) for the development of a bulla; and (2) for the earliest signs of the skin lesion. This last was then described in detail, the method of formation and spread of the bullæ being given, with the appearance presented after their rupture, and their course—(1) in the recovering cases; and (2) in the fatal cases—followed by a short account of the microscopic appearances of sections of an old and a new bulla. The additional symptoms in the fatal cases were detailed, the condition of the umbilicus and abdomen being particularly noticed. It was concluded that these symptoms were those of an acute toxæmia, the infection having gained entrance through the unhealed umbilicus. Notes of the necropsies on Cases 10 and 11 were given, after which the therapeutic measures were discussed and a suggested line of treatment in future cases was laid down. The conclusions arrived at were: 1. This epidemic was one of the comparatively rare disease pemphigus acutus neonatorum. 2. It was due to infection by a pathogenic micro-organism, the staphylococcus pyogenes aureus, conveyed from case to case by a certain midwife. 3. That although it appeared chiefly in the newly born, and was fatal to these only, it also attacked older children and adults. 4. It was characterised by a bullous eruption on the skin, variable in distribution and extent, the specific micro organism being found in the contents of the vesicles. 5 In many of the cases no symptoms other than this eruption were manifested, but a certain number of cases showed grave symptoms of a general infection and invariably ended fatally. 6 The point at which the systemic invasion began in these fatal cases was the unhealed umbilical scar. 7. Treatment to all appearances had little or no effect upon the course and duration of the disease whatever the result.—Dr. C. J. CULLINGWORTH said that one President of the society after another had expressed his regret that so few papers were presented dealing with the diseases of the newly born He therefore thought that [illegible] be specially welcomed as [illegible] iety's claim to embrace within [illegible] and diseases of children. Apart from that, however, the paper was in itself an admirable one and showed a capacity not only for careful and accurate observation but for making clear and painstaking records of such observations. It was interesting to note that in a considerable number of the cases the disease had been communicated to older children and to adults. This fact threw some light upon a case of acute pemphigus which he had himself seen in an adult and which at the time puzzled him extremely. With regard to the special micro-organism that had been discovered in connexion with two of the cases in this remarkable epidemic, he could scarcely bring himself to believe that so widely diffused a microbe as the staphylococcus pyogenes aureus ought to be regarded as the specific source of this particular infection. He was not a bacteriologist and therefore could not speak with authority on this point, but he felt disposed to suggest that on further investigation some infect[illegible] tinctive character would [illegible] with this disorder.—Dr. [illegible] similar epidemic occurred at the Foundling Hospital at Parma in 1901-02 and was described by Dr. Pasini at great length in the *Giornale Italiano delle Malattie Venere e delle Pelle* of this current year. The clinical histories of 14 cases were given, most of which ended fatally; examination of the blood showed a marked leucocytosis, especially in mononuclear cells, pointing either to altered chemiotaxis or to efforts of defence on the part of the subject against pathogenic agents. The cases pointed indubitably to the conclusion that a specific organism was the exciting cause and that there was no relation between this disease and syphilis. Dr. Dickinson thought that the primary mode of infection was not through the umbilical scar which only became infected later through the discharge from the bullæ, general systemic infection with a fatal result then occurring, as shown by Dr. Maguire's cases. The fact that adults became infected also pointed to the same conclusion.—Dr. J. M. H. MACLEOD, after thanking Dr. Routh for giving him the opportunity of being present to hear Dr. Maguire's lucid and scientific report, referred to a few points which had been raised in the paper. He remarked on the increasing rarity of this affection at the present time compared with its prevalence a few years ago, and believed this to be due to the better antiseptic precautions taken in lying-in institutions and elsewhere. He agreed with Dr. Maguire that the disease was due to infection by a pathogenic micro organism, but disputed his conclusion that the specific microbe was the staphylococcus pyogenes aureus, believing it to be a streptococcic infection due to the streptococcus pyogenes or a variant of it. He pointed out that unless special methods were employed in taking cultivations from the skin, and especially from the contents of vesicles or bullæ, cultures of staphylococci would invariably be obtained. He described a method devised by Sabouraud in Paris, in which the contents of the bullæ were aspirated into a sterile pipette containing ascitic fluid after sterilising the skin and the pipette was then incubated for 48 hours at 37° C. By this means Dr. MacLeod had obtained pure culture of streptococci in a fatal case of pemphigus neonatorum. He referred to the relation of this disease to impetigo contagiosa and reminded the members that the initial lesion of the latter disease was a vesicle and that the infective agent was now generally believed to be the streptococcus pyogenes and not the staphylococcus, as was once thought. He noted the occasional occurrence of impetigo contagiosa in the same family as pemphigus neonatorum. He referred also to the close relationship of the disease to the acute pemphigus of adults. With reference to Dr. Maguire's notes on the umbilicus as the seat of infection, Dr. MacLeod believed that in a large number of cases the inoculation did take place there but that it might occur on any abrasion of the skin and mentioned a case in which the mucosa of the lip was the site of infection. With regard to differential diagnosis, he believed that there was no great difficulty in distinguishing this affection from the so-called "congenital syphilitic pemphigus" for various reasons which he detailed, but he considered that it might more readily be confused with the rarer bullous affection known as "epidermolysis bullosa hereditaria," the pathology of which was absolutely different in that it was not due to a microbe but was essentially a condition of excessive vulnerability of the skin in which even slight traumatism resulted in the formation of flaccid bullæ and was probably caused by an instability of the vaso motor system of the skin analogous to that which is present in factitious urticaria.—Dr. P. HORROCKS thought there could be no doubt that pemphigus, as well as many other skin lesions and illnesses, was commoner in the newly born in former times than at present owing to the want of surgical asepsis on the part of the attendants He considered the paper a scientific contribution to the elucidation of the cause of a rare condition but he did not think that the staphylococcus was the culprit, neither did he think with Dr. MacLeod that it was the streptococcus, because both these microbes were so prevalent that it was exceedingly difficult to get rid of them from one's hands. After as thorough a sterilisation as possible the staphylococcus albus could be found under the nails. Hence he thought that pemphigus neonatorum would be common instead of rare if either of these microbes was the cause of it. Probably it was due to some other microbe or else if due to one or both of the above-mentioned germs there must be another factor necessary, which other factor was rarely present. He asked if any of the mothers were ill at all and if they nursed the infants.—Dr. MAGUIRE, in reply, said that the disease was one confined to the skin in the majority of cases and was without symptoms of systemic invasion; where this took place the umbilical scar was always previously involved and the cases ended fatally. It seemed fair, therefore, to conclude that this was the channel by which a simple skin disease became a grave general disorder. Replying to Dr. Horrocks, he said that all the mothers were healthy, with one exception, nor had this woman any grave disease. All the infants were breast-fed.

Dr. W. H. B. BROOK (Lincoln) showed an Ovarian Cyst which had made its way between both broad ligaments, separating the peritoneum from the uterus, the cæcum, and the sigmoid flexure of the colon. The history of the case was as follows. A single woman, aged 56 years, was admitted into the Lincoln County Hospital on April 6th, 1903, for an abdominal tumour which she had noticed since the previous December. She presented all the signs of an ovarian cystoma. The uterus was freely moveable and appeared to be normal. On April 11th the abdomen was opened and the tumour was removed; it proved to be an ovarian cystoma, one large cyst containing 23 pints of thick ovarian fluid with two small loculi. The base of the cyst, which appeared to have originated in the left ovary, extended between the layers of the broad ligaments from one side of the pelvis to the other, passing behind and above the uterus which was buried in the cyst. The peritoneum was stripped off the sigmoid and the cæcum, so that the cyst wall was in direct relation with these, two large layers of vessels spreading over its surface from the mesosigmoid and mesocæcum. The vermiform appendix lay on the upper part of the cyst. As it was impossible to separate the base of the cyst its wall was cut through and the remaining portion was sutured to the abdominal wound and drained. The fundus of the uterus and a subperitoneal fibroid projected into the cyst. This fibroid was cut away and caused no trouble. The patient made an uneventful recovery. A section of the cyst wall consisted of ovarian tissue and showed old corpora lutea. A second section showed the tube stretched out in the cyst wall, its lumen containing a few flattened-out rugæ, and its walls consisting of unstriped muscle arranged in bundles cut across and obliquely.—The case was discussed by Dr. A. H. N. LEWERS, Mr. J. H TARGETT, Mr. MALCOLM, and the PRESIDENT.

Mr. E A BARTON, in showing a specimen of Fœtus Compressus, pointed out that the ovum was passed ten hours after the normal delivery of an eight months living child. The woman had married twice. By her first husband she had had three single children and by her second husband three sets of twins, besides a single child and a miscarriage. There was no history of twins on either side or of syphilis. The fœtus measured seven centimetres by three centimetres but was only five centimetres thick and appeared to be macerated. The cord was ten centimetres long by one centimetre thick The placenta was 7·5 centimetres by 6·4 centimetres but was only 1·75 centimetres thick. It appeared to be normal to the naked eye, though the ovum had remained in utero for five months. On section the placenta showed marked degeneration of the chorionic villi and also in a less degree of the decidual cells.

Dr. LEWERS and Mr. MALCOLM showed specimens of cases of Extra-uterine Fœtation and these were discussed by Dr. HORROCKS, Dr. CULLINGWORTH, and Dr. G. E. HERMAN.

MANCHESTER MEDICAL SOCIETY.

Rheumatic Hyperpyrexia.—Post-operative Hæmatemesis—Acid Auto intoxication.

A MEETING of this society was held on Nov. 4th, Dr. A. M. EDGE, the President, being in the chair.

The PRESIDENT related a fatal case of Rheumatic Hyperpyrexia treated by cold baths. The highest temperature reached was 110° F. Quinine in large doses, cold sponging, continuous application of ice, and even rubbing with ice had failed to reduce the temperature, but immersion in the cold bath was always successful in bringing it down temporarily to a normal or subnormal point. Eight baths were used during the hyperpyrexial period, which lasted seven days, death being preceded by the signs of hypostatic pneumonia. Although the patient was always removed from the bath before the temperature had fallen to 102° collapse frequently ensued, requiring the use of stimulants and hot applications There were very well-marked nervous symptoms, including pain and stiffness in the neck, delirium, clonic convulsions, internal strabismus of the right eye, spasm of the left facial muscles, spasm of the masseters interfering with the opening of the mouth, and protrusion of the tongue. Reference was made to the tetaniform nature of many of these symptoms. The necropsy proved the case to have been one of pure hyperpyrexia without complication except the terminal pulmonary congestion.

Mr. CHARLES ROBERTS read a paper on Post-operative Hæmatemesis with illustrative cases. He described 12 cases, dividing them into two groups. In the first the condition was associated with profound toxæmia and was satisfactorily explained on the theory that it was due to sepsis, the operation acting only as a possible predisposing factor. In the second group the condition occurred apart from sepsis. Three cases were described in detail. The various theories as to the cause of post-operative hæmatemesis were discussed.

Dr. F. CRAVEN MOORE read a communication on the subject of Acid Auto-intoxication *sui generis.* After referring to the clinical and experimental basis of the modern conception of acid intoxication, the prototype of which obtained in connexion with diabetes mellitus, the occurrence of such intoxication apart from diabetes was dealt with and a division of such cases into two groups was adopted—viz. : (1) those in which manifestations of acid intoxication occurred in association with, and probably secondary to, some general morbid state; and (2) those in which they occurred apart from any general disease to which they might be regarded as secondary and apart from any lesions post mortem which would afford adequate explanation of their obtaining to this group, the term acid intoxication *sui generis* being here properly applicable. As illustrative of this condition the following cases from the hospital practice of Professor J. Dreschfeld were described. The first case was that of a female, aged 30 years, who had for some two months suffered from attacks of vomiting, gastralgia, constipation, pallor, and weakness. Four days before death she suffered from drowsiness, prostration, air hunger, and exhibited a strong odour of acetone. The urine gave no reaction for glucose. On admission to hospital the vomiting ceased, the patient became rather excitable, and then lapsed into a comatose condition which terminated fatally in about 20 hours. The urine was highly acid, contained a trace of albumin and no sugar, gave well-marked reactions for acetone and aceto-acetic acid, and also for β-oxybutyric acid. A filtered specimen gave a rotation of – 3° (2 dm. tube); an ethereal extract exhibited negative rotation and crotonic acid was obtained on distillation with H_2SO_4. The second case was that of a female, aged 14 years, who had suffered from recurrent attacks of vomiting and constipation without indications of gastro-intestinal lesion, the condition being apparently "hysterical" vomiting. The breath and urine contained acetone; the latter also contained aceto-acetic acid and β-oxybutyric acid ($\alpha = 0{\cdot}46^\circ$ in 2 dm. tube). With suitable dieting, evacuant enemata, and alkalies internally these manifestations disappeared. The third case was that of a female suffering from mitral disease with broken compensation; she exhibited for a few days acetone, aceto-acetic acid, and β-oxybutyric acid ($\alpha = -0{\cdot}2^\circ$) in the urine. Of these cases the first represented the severe form of acid intoxication *sui generis;* the second to some extent simulated the condition of cyclical vomiting regarded by Edsall as an acid intoxication; and the last was apparently acid intoxication of slight degree and secondary.

LIVERPOOL MEDICAL INSTITUTION.

Pleural Effusion.—Pylorectomy.—Suprapubic Prostatectomy.—Rheumatoid Arthritis.

A MEETING of this society was held on Nov. 5th, Mr. J. RUSHTON PARKER, the President, being in the chair.

Dr. JAMES BARR described his method of treating pleural effusions. After removal of the fluid from 40 to 60 minims of adrenalin chloride, 1 in 1000, were injected. He had used it in many cases with invariable success. In ascites the method was not so successful. He also described an apparatus for the introduction of aseptic air into the pleural cavity.

Mr. F. T. PAUL reported several cases of Pylorectomy. Two patients operated upon *in extremis* died. The other three recovered—(1) a woman, aged 56 years, with extensive cancer of the pyloric end of the stomach who died 16 months later from recurrence; (2) a man, aged 46 years, with an early cancer; and (3) a woman, aged 56 years, in whom the tumour proved to be an inflammatory mass. The two latter patients were so far in excellent health. Mr. Paul also showed a man with Carcinoma of the Pylorus who had improved so much after gastro-enterostomy that he proposed to excise the growth.—Sir WILLIAM M. BANKS said that his experience of removing the pyolrus for cancer was but slight, as he never had any great opinion of the operation owing to the impossibility of removing completely the affected lymphatic glands lying in the curve of the duodenum and embedded in the head of the pancreas. He had operated in about half a dozen cases. They all recovered and for a while appetite returned, weight increased and so on, only to be followed by death in every case. He was not sure whether patients did not live as long and as comfortably with a successful gastro-enterostomy as with excision of the cancer.—Mr. R W. MURRAY said that if a radical cure was to be hoped for in cases of carcinoma of the pylorus the growth must be more freely excised than pylorectomy with union of duodenum and stomach permitted of. In such cases he advocated gastro enterostomy with removal of about one-half of the stomach.—The PRESIDENT remarked that cases suitable for pylorectomy were quite exceptional among cases of malignant disease When he had performed a pylorectomy the narrow duodenal tube had been sewn to the upper part of the wider opening in the stomach and then the redundant remainder of the latter closed.—Mr. PAUL replied.

Mr. G P. NEWBOLT read notes of two cases of Enlarged Prostate treated by Suprapubic Prostatectomy. One patient, aged 70 years, from whom a prostate weighing five and three-quarter ounces was removed in May, 1903, was shown in good health, being troubled only by frequency of micturition. The other patient, aged 62 years, died from uræmia four days after operation. His bladder was shown, the space from which the prostate, weighing one and a quarter ounces, was removed being demonstrated; its base was formed by a well-marked layer of recto-vesical fascia. In both cases the prostatic urethra was torn away together with the ejaculatory ducts.—The PRESIDENT said that he had devoted what attention he could to the perineal method described by their American colleagues, Professor Alexander and Dr. Parker Sims of New York, at the Manchester meeting, 1902. The operation had proved satisfactory to him and to his patients.—Mr. D. DOUGLAS CRAWFORD recognised Freyer's operation as the ideal one. Although easy in adenomatous cases it was difficult in the fibroid form, and he preferred to punch out portions of the prostate in the latter cases.

Dr. C. J. MACALISTER read a paper on Rheumatoid Arthritis and its Relation to other Diseases. He pointed out that the disease as generally seen in institutions was in the stage of deformity and that very often the active processes had been arrested, and he indicated that it was very necessary to treat the disease during its very earliest and acute stages if any real benefit was to ensue. Having referred to the fact that acute rheumatoid arthritis frequently resulted from infections from the nasal, gastro-intestinal, and other mucous membranes, he proceeded to cite a number of examples where rheumatoid conditions had been associated with some perversion of the thyroid functions and stated that the symptoms in these cases had disappeared altogether or had been greatly ameliorated by the administration of thyroid gland. Dr Macalister then proceeded to deal with the early symptoms of rheumatoid arthritis and he pointed out how frequently vascular spasms of the extremities precede the joint affections and also that muscular *cramps were of frequent occurrence as initial symptoms* and he suggested that the poison was very like ergot in its general effects. He considered that there was a close association between Raynaud's disease and some cases of rheumatoid arthritis and, furthermore, that he had seen cases of Graves's disease which suggested that a relationship existed between all three diseases. After referring to the fact that iodine might possibly produce its occasional

this particular poison from the blood and that in order to be eliminated the constitution of the poison had to be changed. In support of this hypothesis he quoted a case where in the acute stage a patient with intensely swollen and painful joints remained unrelieved in spite of the fact that the kidneys and skin were acting profusely until *(all other drugs having failed) large doses of quinine* were given which caused the poison to be poured out through the skin in the form of a horribly smelling, volatile matter which was so offensive that the patient could not be kept in the ward and that with this elimination there were an immediate subsidence of the pains and swellings and a speedy convalescence.—Dr. R. LLEWELLYN JONES (Bath) regarded rheumatoid arthritis as a symptom-complex and thought that given any source of auto-intoxication the resulting toxæmia might through its action on the cord segments produce what was *called rheumatoid arthritis. He emphasised the* importance of the gastro-intestinal tract as a source for such poisons. He alluded to the occurrence of recurrent attacks of local syncope and asphyxia in these cases and also to the presence of muscular cramps affecting mainly the extremities and in others also the muscles of the head and neck. This might suggest a common parent origin, a cerebro-spinal toxæmia, for Raynaud's disease, tetany, and early rheumatoid arthritis. He had also noted the connexion of Graves's disease. Dr. Macalister's *gratifying results with thyroid feeding afforded him much* pleasure, all the more so as he was able to confirm it from his own experience.—The PRESIDENT said he knew from the practice of a friend that feeding was a most important factor in the treatment of these cases. His friend advised the consumption of three pints of milk in addition to the ordinary meals and the President had seen benefit accrue even in some well advanced cases.—Dr. BARR, Dr. G. G STOPFORD TAYLOR, Dr. S. A. GILL, and Dr. W. B WARRINGTON spoke, and Dr. MACALISTER replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Enterectomy for Tuberculous Stricture of the Intestine.—Valedictory Address.—Election of Office-bearers.

THE first meeting of the eighty-third session of this society was held on Nov. 4th, Sir THOMAS R. FRASER, F.R.S., the retiring President, being in the chair.

Dr. NORMAN WALKER demonstrated a case of Multiple Rodent Ulcers on the face of a female patient. The original ulcer on the usual site had healed under the influence of the x rays. At present there were about a dozen small ulcers scattered over the forehead and the face. This multiplicity was important from a diagnostic point of view.

Mr. HAROLD J. STILES showed a boy after Transplantation of Tendons for Paralytic Equino-varus. The long extensors of the leg were paralysed with the exception of the extensor longus hallucis. The peroneal and superficial muscles of the calf were likewise paralysed. The deep calf muscles were active. In the leg both in front and behind the tendons were transplanted into active muscles and the boy now possessed a little movement of the ankle-joint.

Dr. EDWIN BRAMWELL showed a case of Hemiplegia of 12 months' standing in a man, aged 51 years, who had had syphilis 24 years previously. The Argyll Robertson pupil was present on both sides. The right Achilles jerk was absent, although the knee-jerk on that side was markedly

ting pains in his

of opinion that

pre-ataxic tabes.

nost pronounced,

however, on the right side. Stimulation of the sole of the left foot was followed by a flexor movement of the right great toe. The sign of "flexion of the thigh on the trunk," described by Babinski, was present on the right side; the tibialis phenomenon of Strümpell was also well marked on this side.

Mr. A A. SCOT SKIRVING showed two patients after Wound of the Knee Joint. The first patient was a man, aged 52 years, who fell through a glass plate, partially dividing the quadriceps extensor and opening into the knee-joint. *The wound was very dirty. After the application of a* carbolic poultice the wound was enlarged and two large pieces of glass were removed ten hours after the injury. After thorough cleansing of the wound the capsule of the joint was closed and the wound healed by first intention. The second patient was a boy who suffered from acute suppuration of the knee-joint as a result of a wound from a dirty needle. The joint was freely drained and extension was applied. Passive movements were commenced fairly early. The usual statement in text-books was that the best result which could be *hoped for in such cases was ankylosis. It might be that a* more hopeful result was to be expected in children. At any rate the boy shown had very free movement in the knee-joint.

Mr. DAVID WALLACE showed: 1. A lad, aged 19 years, who suffered from a Congenital Hypertrophy of the Left Half of the Tongue. The left half was twice the size of the right and had a papillomatous appearance and varied in size from time to time. The latter condition was noted in a case recorded by Hutchinson. 2. A man who had a Dislocation of the Acromial End of the Clavicle which had been *treated by wiring. Though the movement was very good the* bone was not in proper position.

Dr. W. ALLAN JAMIESON showed: 1. A case of Parakeratosis Variegata in a woman, aged 35 years. The disease commenced eight years ago and at present the whole body was more or less affected, the skin of the trunk and limbs being of a deep crimson red colour shading into brown in places and dotted over with white spots. The epidermis seemed to be looser on the cutis than normally. The surface was glossy like silk and itchiness was complained of. Much *improvement had resulted from the use of glycerine of starch* with 40 grains of resorcin to each ounce. 2. A case of Mycosis Fungoides in the erythrodermic stage. The patient was a woman, aged 49 years, and almost the whole body was covered with ill defined brick-red patches or slightly roughened yellow areas on parts of which were crusts. The inguinal and cervical glands were enlarged. As yet there were no tumours. Exposure at a distance of ten inches to the x rays was being tried as treatment. 3. A patient to show the Results of Treatment in a severe case of Ichthyosis. The lad, *aged 16 years,* had been *treated* by daily washing with a resorcin and salicylic soap, followed by inunction twice in 24 hours with glycerine of starch containing a drachm of resorcin to the ounce and with marked benefit. 4. A case of Ichthyosis showing unusual distribution. The girl, aged 13 years, showed on the palms and the soles great thickening of the epidermis, that on the soles being more than a quarter of an inch in thickness. At the bend of each elbow and in the axillæ large areas were covered by an almost black filiform growth interspersed with fine hairs. The same condition was present on the nipples and their areolæ, the flanks, the front of the abdomen, the groins, the patellar area, the popliteal spaces, the ankles, and the front of the toes. The appearances were those of ichthyosis hystrix.

Mr. J. M. COTTERILL exhibited a man with a Sarcoma of the Shoulder at present being treated with the x rays.

The following card specimens were shown:—

Dr. A. HILL BUCHAN: Two Microscopical Preparations from a case of Asthma.

Mr. SCOT SKIRVING: (1) Stereoscopic Photographs of a series of Extragenital Chancres; and *(2) Specimen and* Photograph of a peculiar Foreign Body (Extremity of a Locust Bean) impacted in the Left Bronchus.

Mr. COTTERILL: (1) a Large Multiform Ovarian Cyst; (2) a Kidney removed from a child, aged five years, for hydronephrosis due to congenital occlusion of the ureter; (3) a Tumour removed from the gluteal region of a child, aged nine months (with slide); and (4) Specimens to illustrate longitudinal splitting of the internal semilunar cartilage in so-called "dislocation" of that structure.

Mr. F. M. CAIRD: Specimens of Stricture of the Bowels.

Mr. CAIRD read a paper entitled "Enterectomy for Tuberculous Stricture of the Intestine." He said that there were but few papers upon, and scanty attention had been given to the subject of, tuberculous stricture of the intestine in English medical literature and that they owed their knowledge of the condition mainly to continental authorities. Therefore the experience derived from the cases to be shortly related might be of some value from a diagnostic, prognostic, and therapeutic point of view. Tuberculous stricture appeared to be most frequent in early life, up to 30 years of age, and became rarer with advancing years. It was interesting to note, however, that four of the following patients were over 30 years of age. The disease favoured the sexes alike although they might anticipate that extension from the Fallopian tubes might predispose to its more frequent occurrence in the female. In Mr. Caird's cases marked stenosis was due to three very definite varieties of fibrous hyperplastic change. The most frequent type was that in which zones of tuberous papillary projections developed to a variable extent. At the maximum point of stenosis annular constrictions might also occur and might so encroach on the lumen as almost to cause obliteration and to convert it into a narrow tunnel. Both forms had been observed in one patient. A solid bobbin-like mass strongly suggestive of a new growth was discovered on one occasion. Forms intermediate between all the above abounded. The cæcum and the lower part of the ileum were the favourite sites. The ileo-cæcal valve and the cæcum were affected in six of the cases. The appendix was then lost in the general mass of proliferated tissue and could only be recognised by making sections. In four cases the small intestine only suffered. There was a tendency to the formation of fresh zones of hyperplastic growth in the distended hypertrophied gut immediately above the level of the main stricture Multiple strictures might, however, exist with some intervening areas of healthy gut The diagnosis of the cases during life might present considerable difficulty and they had to differentiate between the inflammatory mass of a chronic appendicitis, the varieties of malignant disease, and the other swellings which might be found in the ileo-cæcal region. When the small intestine was alone at fault the recognition became simpler. The clinical features usually presented a long history of failing health and indigestion associated with progressive emaciation. The bowels were usually constipated and purgatives were generally required. Severe colic pain and tenderness became gradually pronounced and very loud borborygmi annoyed the patient and were audible to bystanders Vomiting might be frequent and often afforded relief. Hæmatemesis was not met with nor yet diarrhœa or the passage of blood, although piles might co-exist. The abdomen became swollen and tense and ladder-like patterns and marked peristaltic waves were seen. A tumour might be palpated in ileo-cæcal cases. Owing to the site of the lesion the cases were chronic and the stricture must be very tight, be blocked with some foreign body, or be complicated by adhesions to adjacent coils of intestine before complete obstruction with its usual manifestations developed. The principles common to enterectomy for malignant disease, gangrene of the bowel, &c, guided them in dealing with tuberculous stricture, but the operative measures were frequently more difficult, and this was especially the case when they had to deal with adhesions. The surgeon might shell out a loop of intestine affected with carcinoma from a mass of surrounding dense inflammatory tissue, as was well seen in cases of adherent cæcal and sigmoid tumour, but in tubercle there was greater infiltration and while carcinoma might be shut in by the new fibrous tissue the tuberculous process frequently burst through the muscular and serous coats and infiltrated widely. The free non-adherent strictures of the small intestine gave rise to less trouble, but in any case an anxious element existed in the form of extensive implication of lymphatic glands which might necessitate a far-reaching removal of mesentery and entail the sacrifice of healthy intestine. Or again some of the caseating glands might have softened or suppurated and might rupture into the peritoneal cavity during manipulation and so determine a fatal issue. In operating, then, the patient should be suitably prepared and the surgeon should cut wide of the diseased area and see that a distended intestine above the stricture was thoroughly emptied. It was always important to plant the sutures in healthy non-congested bowel. There were three series of cases to be dealt with 1. If the stricture be localised, solitary, and non-adherent, it should be divided well above the proximal dilated portion, since there was a tendency for the development of secondary tubercle at points of erosion and ulceration above the primary lesion. Should there be multiple strictures separated by a lengthy interval of healthy intestine, it was better to deal with each stricture individually than to sacrifice a huge stretch of the alimentary canal. 2. In dealing with an area of matted coils it was advisable to ascertain in the first instance the extent and relation of the parts involved; the surgeon must then carefully identify the free healthy proximal and distal intestine and applying clamps proceed to remove the entire mass. The mesenteries might be divided close to their origins as this entailed the ligation of fewer, if larger, vessels and allowed the operator to remove all the lymphatic glands. Since the latter could not well be dissected out without damage to the blood-supply of the intestine it might be necessary to remove much bowel in clearing away the infected glands. Should the mass at any point be firmly adherent to an adjacent healthy loop it would appear needful to resect that loop also or to resect the implicated wall and so to avoid the possibility of leaving a future focus of disease. 3. When there were numerous adhesions of coils, not only to each other but also to adjacent structures and the implicated mass could not be liberated without grave risk, it might be safer to sever the healthy proximal and distal coils of gut and to unite them end to end; the divided lumina in connexion with the diseased area might be conducted externally so as to open on the abdominal wall. It was also probable that a short-circuiting by lateral anastomosis in such circumstances might give better results than any other method of treatment. Of 11 patients subjected to enterectomy seven recovered and four died. The amount of intestine resected had varied with the size and situation of the stricture, the condition of the gut above, its adhesions, and the extent of lymphatic glandular infection. In one patient double enterectomy was practised with the removal of two strictured portions, five and eight inches respectively in length. In one other 40 inches of small intestine and in a third no less than 80 inches, including the cæcum and greater part of the ascending colon, were resected.

Table of Cases of Enterectomy.

No.	Age (years, and sex.	Condition.	Operation.	Result.	After-history.
1	9, M.	Ileo-cæcal; quiescent; tuberculous stricture.	Resection, 1899.	Recovery.	Well.
2	7, F.	Ditto; many enlarged and caseating glands	Resection, 1895; secondary suture.	"	"
3	24, M.	Ascending colon; extensive matting.	Resection, 1890.	Died; fæcal infection.	—
4	12, M.	Ileum.	Resection of six inches, 1891; primary suture.	Recovery.	Well.
5	61, M.	Ileum; extensive infection of mesenteric glands.	Resection of 80 inches, 1901; secondary suture	"	Died; recurrence.
6	68, M,	Ileum; matting of glands.	Resection of 40 inches, 1901; primary suture.	"	Died; cardiac failure
7	57, M.	Ileum; two strictures.	Double enterectomy, 1901; primary suture; 13 inches.	"	Died; recurrence.
8	34, F.	Ileum; cæcum; Fallopian tubes.	Resection, 1902.	Died.	—
9	30, F.	Ileum; cæcum.	Resection of seven inches, 1902; primary suture.	Recovery.	Poor health; fæcal fistula.
10	34, M.	Ileum; glands suppurating	Enterectomy, October, 1903.	Died.	—
11	46, M.	Ileo-cæcal and ileum.	Double enterectomy, 1903.	"	—

The patients did not seem to suffer inconvenience from this excessive loss of intestinal surface. In regard to the further history of the cases the three young patients recovered and continued well. The three elderly men did not long survive. The eldest, aged 68 years, made a good recovery but suddenly dropped dead from cardiac failure. The two others, after enjoying a short period of renewed health, succumbed to emaciation and general enlargement of the whole mesenteric and abdominal lymphatic glands. In these three cases a section was obtained and each showed evidence of old pulmonary tubercle. The sites of junction were perfectly patent without the slightest trace of contraction. There was evidence, however, of the formation of further stenosed and ulcerated areas and a fistula bi mucosa existed between the lower part of the ileum and the sigmoid in one instance. A fæcal fistula developed some months after resection of the ileo-cæcal region in one weakly patient. A second exploration revealed extensive matting and lateral anastomosis was then performed but without marked benefit ensuing. Malignant disease was associated with tubercle in two cases of ileo-cæcal tubercle and colloid cancer and probably in one other case sarcoma was associated with the local condition in the small intestine.

The retiring PRESIDENT then delivered his Valedictory Address. He said that the record of the society was that of its members and that success or the contrary must largely depend on the vigour and activity that were brought to the society by the number of the members who took part in the proceedings. It was therefore gratifying to find that since the end of 1901 the membership had increased by 33, the total number of ordinary members being now 426. The President then gave a record of those honorary and ordinary members who had died during the past two years and paid tributes to Virchow amongst the former and to Dr. Stewart Stirling and Dr. R P [illegible] non-resident member [illegible] names of Dr. George [illegible] Dr. W. S. Playfair ar [illegible] and Dr. Archibald Dickson stood our prominently. The most important work of the society consisted in the original communications read before it and during the past two sessions 36 such communications had been given. 28 of these related to medicine and eight to surgery. Curiously enough, and in contrast with previous years, papers dealing with the heart and circulation were absent. The nervous system, special therapeutics, and affections of the respiratory apparatus were the groups most largely represented. The aims and endeavours of the society were not, however, limited to the diffusion of professional knowledge amongst its members, but also included the advancement among the general public of improvements and reforms in the prevention and treatment of disease and the promotion before a wider public than was usually present at the meetings of schemes which appeared likely to promote the social and the physical well-being of the inhabitants of the country and upon which they were convinced the prosperity of the nation was largely dependent. Sir Thomas Fraser did not think that there had been any lack of endeavour in these directions during the two years in which he had occupied the President's chair. He referred to the fact that after careful consideration the society last year resolved to petition the town council to continue the notification of measles and although the request had not been acceded it was probable that some practical results would be obtained. In that year also at a special meeting largely attended by representatives of the chief public and social institutions of the city an important discussion took place on the advisability of more largely providing for the treatment of incipient and transitory mental disorders in wards connected with the Royal Infirmary. A recommendation so influentially advanced naturally received careful consideration from the managers of the Royal Infirmary, but difficulties had arisen at present in providing this necessary accommodation. When this temporary obstacle had been removed there was reason to believe that the recommendation of the society would be realised, to the great advantage of a deserving section of their fellow men and of the public generally by the increase that would thereby be gained in the educational resources of the medical profession and the consequent enhanced ability of the members of that profession to cure disease. In the meantime the action of the society had rendered it probable that a much-required improvement would soon be effected in the organisation of the wards of the Royal Infirmary. A second special meeting was also held in the hall of the Royal College of Physicians of Edinburgh for the purpose of discussing the prevention of pulmonary phthisis and the notification to the sanitary authority of cases of that disease. A motion was adopted at that meeting favourable to compulsory notification, but at the same time several of the speakers expressed themselves with some hesitation on the adoption of this extreme measure, mainly, the President thought, on the ground that there would thereby be thrown upon the sanitary authorities responsibilities which they could not undertake. On that occasion the President had stated that he felt much doubt whether material benefit would be gained by isolation because of its impracticability or by a diffusion of knowledge because of its probable barrenness of results among the least enlightened members of the community, or by such precautions as the prohibition of expectoration in streets and public places because of the impossibility of carrying it into effect and of the probability that in the open air of streets tuberculous sputum was not an important danger. More benefit, he thought, would be gained by the adoption of the relatively simple measures which were required to improve the health and to increase the physical strength of all classes and especially of those who occupied the lower stratum of society. All experience had shown that the chief and at the same time essential of these simple measures, with which at the present time there was no competing rival, was the providing of sufficient pure air, light, and space in dwelling houses. It was to all intents a special meeting at which Dr. T. S. Clouston, the President of the Royal College of Physicians of Edinburgh, initiated a discussion on the Scottish Medical Corporations and the Common Weal: how they might Develop a Health Conscience. With his great courage and untiring energy the author of this proposal was, he believed, still engaged in the work of carrying it to a practical issue. The President referred with satisfaction to the institution of clinical meetings in the Royal Infirmary and in the Sick Children's Hospital and to the large attendance of members at the meetings as contrasted with former years as well as to the satisfactory condition of the funds of the society. In concluding, he thanked the members for the high honour which they had done him in electing him two years ago to the distinguished position of their president and felt it a great pleasure and gratification that under the direction of his successor, Professor Chiene, the society would have the best of prospects of continuing its career of prosperity and of maintaining its usefulness.—On the motion of Dr. CHARLES E. UNDERHILL a cordial vote of thanks was awarded to the President for the able and kindly manner in which he had fulfilled the duties of the chair.

The following gentlemen were elected as office-bearers for the session 1903-04. President: Professor J. Chiene, C.B. Vice-Presidents: Sir John Halliday Croom, Dr. James Ritchie, and Dr James Ormiston Affleck. Councillors: Dr. Edward Carmichael, Dr. Thomas B. Darling, Dr. William Stewart, Dr. William George Sym, Sir Thomas Fraser, Dr. Charles E. Underhill, Dr. Dawson F. D. Turner, and Dr. Norman Walker. Treasurer: Dr. H. Harvey Littlejohn. Secretaries: Mr. H. Alexis Thomson and Dr. G. Lovell Gulland. Editor of Transactions: Dr. William Craig.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The first ordinary meeting of the session of this society was held on Oct. 28th, Mr. W. B. Holderness, the President, being in the chair.—Dr. Fletcher Beach delivered an address entitled "Types of Weak-minded Children met with in Daily Practice." The address was illustrated by lantern slides. He described 13 types and gave examples of each. The first was the simple congenital type, in which there was no marked deformity of the head or the limbs. Photographs of six of these cases were shown, three being of a low type and three of a higher type. Next he described the Mongolian type, so called from a resemblance in facial characteristics to the Chinese physiognomy. A group of cases exhibiting these characteristics was shown and the history of a typical case was given. Dr. Fletcher Beach then passed to the cretin il type and described the symptoms met with in cases that had not undergone the thyroid treatment, illustrating them by the photograph of a group of five cases. He then showed a case before and after the treatment and mentioned the differences in the symptoms which were seen after the patient had been under the treatment. He said that it was necessary to watch the patient carefully, for if he should lose weight too rapidly, or if the temperature and pulse should rise much above normal, the treatment must be stopped for a time or the dose must be reduced. The microcephalic type was next described and it was shown that heads of this kind were much smaller than normal. The microcephalic brain was also smaller than it should be and, moreover, was incompletely developed. The parts chiefly affected were mentioned, a photograph of a microcephalic brain being thrown on the screen to make these differences more clear. Two cases of this type were also exhibited and their histories were described. Very different from this type was the hydrocephalic in which the heads were larger than normal. The characteristics of this type were pointed out and the histories of two cases were fully given. A type which was sometimes mistaken for this was the hypertrophic, in which the brain was larger than normal. The diagnosis between the hydrocephalic and the hypertrophic types, which was described by Dr. Fletcher Beach some years ago, was given at length. Photographs were exhibited showing the differences between the two shapes of head and the history of a case illustrated by photographs was given. Another important type was the traumatic in which the defect was due either to a fall or a blow on the head or injury to the head during birth. In this type the degree of mental deficiency varied with the extent of the destruction of brain tissue and the presence or absence of hereditary predisposition. Closely allied to this type was the eclamptic in which convulsions supervened soon after birth, continued for some years, and then ceased, but the effect on the brain was so injurious that the child became mentally deficient. The histories of two such cases were mentioned and a photograph was shown. The epileptic type included patients who recovered under treatment, patients who improved considerably, others who remained stationary, and others who deteriorated and became demented. Photographs were exhibited of each of these classes and the history of a case which remained stationary was described. Another important type was the inflammatory or post-febrile, in which the mental deficiency came on after an attack of measles, whooping-cough, typhoid fever, or scarlet fever. Many children of this type did remarkably well under training; two photographs were exhibited and the histories were given. A type frequently met with was the paralytic and the paralysis might occur before or after birth. An illustrative case of each class was described and photographs were shown. A less frequent type was the scaphocephalic in which the patient presented a keel-shaped head—narrow from side to side and elongated from front to back. A case of this kind was described and a photograph was shown. Finally, Dr. Fletcher Beach mentioned the feeble-minded, which type was a much higher type than those which had been previously described. Three photographs of this type were shown and the history of one who was employed as a shoemaker was given. He had considerably improved in school work before being sent out to pass the whole of his time in the shop.—A vote of thanks to Dr. Fletcher Beach for his interesting address terminated the proceedings.—The annual dinner of the society took place after the meeting at the White Hart Hotel. There was a good attendance of members.

Midland Medical Society. — The second ordinary meeting of this society was held at the Medical Institute in Birmingham on Nov. 4th, the President, Dr. Robert Saundby, being in the chair.—Dr. J. R. Charles showed a case of Huntingdon's Chorea in a woman. A peculiar feature of the case was that of all the cases occurring in the patient's family—three generations—the majority were females. The patient presented the usual features of the disease, the movements especially being characteristic.—Dr. J. Douglas Stanley stated that the patient had formerly been under his care at Queen's Hospital and that this was the third instance occurring in Birmingham within the last nine years of a family affected with Huntingdon's chorea. He considered that no clinical difference could be drawn between Huntingdon's chorea and senile chorea, except that of a family history in the former.—The President referred to cases of senile chorea formerly under his observation and considered that they were quite distinct in character from Huntingdon's disease.—Dr. Charles, in reply, considered that senile chorea was a sporadic instance of Huntingdon's disease—Dr. C. E. Purslow reported that at the March meeting of the society he showed a specimen of Uterine Appendages with a small body situated in the broad ligament close to the ovary which he had ventured to call an accessory ovary. This body bore an exact naked-eye resemblance to the ovary near which it lay and at the meeting none of the members present who examined the specimen raised a doubt as to its being an accessory ovary. A microscopical examination had not then been made, as to have done so would have destroyed the specimen. Sections had, however, since been cut and these clearly showed that the nodule was a small fibroma and did not contain any ovarian structures.—Mr. Jordan Lloyd showed a specimen of Enucleated Prostate and also a Vermiform Appendix which presented a well-marked stricture and a dilatation beyond. Mr. Jordan Lloyd then read a paper entitled "The Pathology and Treatment of Diseases of the Natural Cavities and their Ducts." He instanced the condition of the urinary bladder, the appendix, the bronchi in cases of obstruction, and especially the stomach when there was pyloric obstruction. He was rather inclined to believe that when gastric dilatation existed there was obstruction to the outlet through the pylorus and that, therefore, the rational treatment was to relieve the obstruction.—Mr. William Thomas referred to a case quoted by Mr. Jordan Lloyd in which tracheotomy had given relief to a patient with cicatricial contraction due to cut-throat.—Dr. Stanley asked Mr. Jordan Lloyd if muscular defects were not competent to cause gastric dilatation. He thought that every case of dilated stomach should be taken on its merits and that every means should be taken to ascertain its cause before resorting to operative procedure.—Dr. T. Nelson referred to a case of aortic aneurysm in which there were marked bronchial symptoms.—Dr. Walter R. Jordan asked Mr. Jordan Lloyd how he would decide clinically between cases of gastric dilatation due to pyloric obstruction and those the existence of which he believed to be due to muscular relaxation.—The President referred to the important aid to diagnosis obtained from examination of the gastric contents in the morning as ascertained by means of the stomach tube. In cases of primary gastric dilatation no food material could be found in the morning. He believed primary dilatation of the stomach to be a rather frequent condition. In his own practice he found modern methods of gastric investigation of great service if only in indicating cases that should be treated surgically.—Mr. Jordan Lloyd, in reply, deprecated undue haste in forming an opinion in all gastric cases and said that the interests of the patient required that medical treatment should have a fair trial. He was still of opinion, however, that many cases of gastric dilatation could only be relieved by surgical means.

Society of Anæsthetists.—A meeting of this society was held on Nov. 6th, Mr. C. Carter Braine, the President, being in the chair.—The Senior Secretary read for Mr. Norman Bennett, who was unable to be present, notes of a case of Death under Nitrous Oxide. The patient was a youth, 17 years of age, who suffered from enlarged cervical glands. He showed no dyspnœa and had had nitrous oxide a few days previously without any untoward symptom. "Gas" with air was administered for extraction of teeth by an assistant. The face piece was removed before stertor occurred; the patient became more cyanosed and ceased to breathe. During artificial respiration several spontaneous attempts at respiration were made. An attempt to perform a low tracheotomy was unsuccessful. It was afterwards found that the patient had been suffering from dyspnœa associated with stridor and had had respiratory difficulty on another occasion when nitrous oxide had been administered. The necropsy showed that there were enlarged glands in various parts of the body and that the diameter of the trachea was reduced by one-half. The heart muscle was degenerated. The following took part in the discussion: the President, Dr. J. F. W. Silk, Dr. J. Blumfeld, Mr. W. Tyrrell, Mr. J. H. Chaldecott, and Mr. H. Hilliard.—Dr. Moritz read a paper on the Combined Administration of Nitrous Oxide and Ethyl Chloride by Dr. Hewitt's Method. Dr. Moritz's experience extended to 350 cases. He said that the anæsthesia obtained was deeper and longer than that after any other anæsthetic for dental operations in one administration. The average operative anæsthesia is about 60 seconds though often much more, while struggling, cyanosis, and muscular rigidity are absent. Recovery is not so quick as after "gas" or "gas" and oxygen but is more rapid than after somnoform and ethyl chloride. The patients were not prepared for anæsthesia. With regard to after-effects, vomiting appeared in about one case in seven and was variable in degree up to three hours. Headache was fairly common but usually did not last long. Vertigo occurred in a few cases. Hysterical demonstrations and in men violent hitting out occasionally were seen. The conjunctival vessels were injected. Different brands of ethyl chloride gave the same results. The severity of after-effects seemed to depend on the absence of dieting and the quick resumption of the erect posture. Under favourable conditions the combination in question was the finest anæsthetic at present at their disposal for short operations.—The paper was discussed by the President, Dr. Bakewell, Mr. Chaldecott, Dr. Scharlieb, Dr. Noble, Dr. Blumfeld, Dr. R. J. Probyn-Williams, Dr. Silk, Dr. G. B. Flux, Mr. Hilliard, Dr. McCardie, and Mr. Wallis —Dr. Moritz then replied.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 30th, Dr. A. F. Street, the President (Westgate-on-Sea), being in the chair.—The President delivered an address on Some Questions in Seaside Climatology. He suggested that there were physical differences between the atmospheres of different places beyond those comprised in the factors ordinarily considered as constituting climate and it was contended that this view was borne out by more or less generally [illegible]ity of certain diseases s[illegible] of cases imported in [illegible] adduced to show that ozone had been credited with too great a share in the stimulating properties of sea air, that its prevalence had not been completely demonstrated, and that the salts diffused by spray could not have a notable therapeutic effect. The questions of a percentage of oxygen and of the possible influence of the rarer atmospheric gases, of atmospheric electricity, and of any physiological effects of radio-activity and its presence in sea air and sea water were raised. Reference was made to the principles governing the selection of climates for invalids and to the public duty of avoiding pollution of the atmosphere.—Dr. Leonard Ll. B. Williams proposed, and Dr. G. W. Hamilton Cumming (Torquay) seconded, a vote of thanks to the President for his address.—The President replied.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Nov. 5th at which Dr. J. A. Ashcroft, the President, gave an address on Appendicitis. After some remark[illegible]n the various morbid conditio[illegible] iliac fossa, the causation of [illegible] There were four varieties clinically (1) slight cases amenable to medical treatment; (2) more severe cases with the formation of abscess; even some of these might yield to non-operative treatment; (3) acute perforating cases which required operation; and (4) relapsing cases. Pain was frequently referred to the back or to the inner aspect of the thigh. As regards treatment the general principles were rest, the withholding of food, and the avoidance of opium. Opinions differed as to the time for operation, American surgeons inclining to operate early, while British surgeons, generally speaking, preferred expectant treatment at first and operation between attacks. Patients liable to appendicitis should be careful as to what they ate, should have regular meals, and should avoid hurry.—Mr. S. T. Lord, Mr. W. Pooley, Dr. H. Brooks, and Mr. H. H. I. Hitchon joined in the discussion, Dr. Brooks stating that he had had two severe attacks of appendicitis and had undergone operation; he gave his personal experiences.—The President was cordially thanked for his address.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND —At a meeting held on Oct. 28th, Dr. J. H. Stowers, the President, being in the chair, Dr. P. S Abraham showed: (1) A case of Xanthoma Diabeticorum; and (2) a case of Scleroderma.—Dr. E. G. Graham Little showed: (1) A case of Epithelioma which had developed on the site of a nævus; (2) a case of Symmetrical Gangrene of the Auricles; and (3) a case of Elephantiasis —Mr. George Pernet showed: (1) A case of Secondary Hirsuties on the site of a cleared-up lichen patch; and (2) a case of Lupus Erythematosus Disseminatus.—Dr. G. Norman Meachen showed a case of Persistent Purpura.—The President showed: (1) A water-colour drawing of a case of Peliosis Rheumatica; (2) two cases of Tertiary Syphilis; (3) a case of Rodent Ulcer which had been recently operated upon; and (4) a case of Lupus Erythematosus.—Dr. V. H. Rutherford showed a case of Lichen Planus.—Dr. T. D. Savill showed a case of Hypertrophic Scarring after Variola —Mr. Arthur Shillitoe showed: (1) a case for Diagnosis; and (2) two cases of Syphiloderma.—Dr. Wilfrid B. Warde showed a case of Extensive Hypertrophic Scarring after Typhoid Fever.—Dr. Alfred Eddowes showed a photograph and microscopical sections of a case of Cyst-adenoma of the Sebaceous Glands.

EDINBURGH ROYAL MEDICAL SOCIETY —A meeting of this society was held on Nov. 7th, Dr. Fitzwilliams being in the chair.—Dr. Shaw, Senior President, gave from the chair his presidential address, his subject being the Relation of Medical Men to the Community with Special Reference to the Improvement of National Physique.—Dr. Fletcher showed a case of Pseudo-hypertrophic Paralysis occurring in a man, aged 23 years. The calf muscles, the biceps, and the triceps were especially enlarged; while the gluteal muscles and the trapezius and the latissimus dorsi were atrophied. The patient showed the characteristic attitude when standing and also "climbed up his knees" in rising from the floor He had so far improved under treatment —Dr. Fletcher also showed a case of Senile Chorea in a male patient, aged 36 years. The symptoms had been present, gradually increasing, for six years. Some points in the case suggested an element of malingering or that it might be an unusual case of general paralysis of the insane.—Dr. Morton read notes of a case of Acute Bright's Disease with uræmic convulsions. The prognosis and treatment were complicated by the presence, in addition to the kidney disease, of alcholic cirrhosis of the liver, acute apical pneumonia, and ichthyosis. The kidney showed evidence of an acute nephritis superadded to old-standing disease.

GLASGOW SOUTHERN MEDICAL SOCIETY.—This society met for the first meeting of the session on Oct. 29th, Mr. Thomas Richmond, the President, being in the chair. There was a good attendance of members to hear the President's address on *Reminiscences of my Student Days* and of Thirty-six Years of Practice. A reference was made to the days when darkness became light at the dawn of Listerism. After paying a warm tribute to Lord Lister the President reverted to the old Andersonian College as it was when situated in George-street. Of his old teachers, giants in the medical school of Glasgow 40 years ago, he spoke with deepest reverence, and tracing proudly the careers of those still surviving he alluded to the high positions which they now occupied in the medical world. The great advances which had been made in medical science within the last 40 years were next touched upon and an earnest appeal for a thorough review of the present treatment of inebriety was made —On the motion of Dr. D. Macgilvray, Mr. Richmond was thanked for his address.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—At a meeting of this society held on Nov. 6th Mr. A. N. Ross read a paper on Renal Surgery, its Rise and Progress. He rapidly sketched the various operations, discussing the indications for the use of each and ably criticising recent developments —Mr. J. Robertson followed with a paper on the Therapeutics of Light in which he traced the use of light in medicine from Finsen's time up to the present day. The structure and the use of the Finsen lamp and its modifications were well demonstrated.—Interesting discussions were held on both papers and votes of thanks to the lecturers, which were heartily accorded, brought the meeting to a close.

GLASGOW NORTHERN MEDICAL SOCIETY.—The second meeting of the session of this society was held on Nov. 3rd, Dr. A T. Campbell, the President, being in the chair.—Dr. J Lindsay Steven read a very interesting and instructive paper entitled "The Surgical Treatment of Gastric Disease from the Physician's Point of View."—A discussion followed in which several members took part.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—The annual meeting of the subscribers to the West of England Eye Infirmary, Exeter, was held on Oct 30th, under the presidency of Mr. F. Hamlyn. The medical report stated that 3318 patients had been treated during the 12 months ended Sept. 30th last, the daily number of in-patients being 45. The financial statement showed that the ordinary expenditure had exceeded the income by £185. Dr. L. H. Tosswill who had resigned the post of honorary surgeon to the institution was appointed honorary consulting surgeon. The high sheriff of the county (Sir Thomas Acland) was elected president for the ensuing year.

Reviews and Notices of Books.

The Principles of "Open Air" Treatment of Phthisis and of Sanatorium Construction By ARTHUR RANSOME, M.D., M.A. Cantab., F.R.C.P. Lond., F.R.S., Consulting Physician to the Manchester Hospital for Consumption and Diseases of the Chest and Throat London: Smith, Elder, and Co. 1903. Pp. 104. Price 5*s.*

THIS volume consists of four essays dealing with various aspects of the "open-air" treatment of pulmonary tuberculosis. The first essay is entitled the "Principles of Sanatorium and Open-Air Treatment of Phthisis." A good and explicit account is given of the various factors which take part in systematic sanatorium treatment and of the advantages and possible disadvantages of this therapeutic measure. Dr. Ransome's remarks on "Diet and Full Feeding" are well worthy of attention. There is a tendency on the part of some physicians when directing a course of "open-air" treatment to follow slavishly certain general rules in the way of diet. This is an error; success consists in the individualisation of patients; each case must be carefully considered with regard to its own peculiarities. As Dr. Ransome expresses it: "We must beware of a mere mechanical adherence to fixed rules; our aim, on the contrary, should be true physiological feeding." To compel patients to eat three heavy meals daily, in spite of frequent vomiting, can hardly be altogether beneficial and we believe Dr. Ransome to be perfectly correct when he says, "The after-histories of some of the best examples of cures turned out by this or that sanatorium conducted on this system frequently show dilated stomachs or even damaged kidneys." Dr. Ransome also refers to the importance of gain in body-weight. Doubtless this circumstance is of no small importance; it conduces to ultimate cure, encouraging patients when they need all the perseverance they can command. Stress, however, might have been advantageously laid on the fallacious character of increase in weight. It is frequently found that although a patient may gain a stone or more in weight, nevertheless the physical signs and temperature chart indicate that very little substantial progress has been made. Gain in weight therefore is only of value when taken in conjunction with other marks of improvement.

The second essay is headed "On Certain Bodily Conditions resisting Phthisis." Careful consideration is given to points concerning the natural immunity of man to tuberculosis, but the most interesting part of this essay, to our minds, is the account of the condition of the blood in pulmonary tuberculosis and in those diseases which are usually considered to be antagonistic to that malady. The increase in the number of the red blood corpuscles in those patients under going the open-air treatment is remarkable; in one case 7,600,000 were found per cubic millimetre. Dr. Ransome believes that the success of sanatorium treatment may to some extent be explained by its blood-making power—"a power which may even have to be pushed beyond the limits of perfect health." This theory is not out of accord with the explanation usually given of the *rationale* of open-air treatment—namely, that by it the resisting powers of the tissues are greatly increased.

The third essay is concerned with the "Principles of Sanatorium Construction," and a diagram of the plans of a sanatorium has been prepared by Mr. G. A. Bligh Livesay, F.R.I.B.A. The general scheme is a good one but we have not space to criticise it thoroughly.

The last essay is on the "Pure-air Treatment of Phthisis at Home." We agree with Dr. Ransome that the open-air treatment can be carried out more perfectly in sanatoriums than in most private houses but there are many persons who will not leave their homes; and also there are those who, having been educated as to the manner of life they should lead in a sanatorium, appreciate the advisability of continuing it on their return to domestic life. Dr. Ransome details the precautions which have to be observed and the steps which must be taken to carry them out.

This little volume will be found a most interesting one and we can cordially recommend it to our readers.

Nothnagel's Encyclopædia: Diseases of the Stomach. By FRANZ RIEGEL Edited with additions by CHARLES G. STOCKTON, M.D. Authorised translation from the German under the editorial supervision of ALFRED STENGEL, M.D. London, Philadelphia, and New York: W. B. Saunders and Co. 1903 Pp. 835 Price 25*s.*

IT has recently been very forcibly urged that facilities for original and scientific research in clinical medicine are most inadequately provided for at our centres of medical education. Laboratory research proceeding hand-in-hand with clinical observations in the wards is an essential combination for the progress of medical science and for the solution of many problems in pathology which are of vital importance. In no field of medicine does a combined experience in laboratory and clinical methods constitute a more desirable qualification for practice or more richly repay the student who has availed himself of this dual method of research than in that branch of medicine which is concerned with diseases of the stomach and disorders of digestion. At many of the universities in Germany, France, Russia, and America the chairs of clinical medicine are occupied by professors who devote themselves to some particular branch of medicine and who attract to their clinics a large following of young qualified practitioners who give their time exclusively to research work in the laboratories and in the wards along the special lines of inquiry pursued by their chiefs, and in this way by the collective industry of a large number of workers a clinic such as that of Professor Riegel becomes a recognised centre for the acquisition and distribution of special knowledge. The clinics on the continent concerned with the study of the diseases of the stomach and of disorders of digestion include among others those of Riegel, Kussmaul, Ewald, Bouchard, and Pawlow; of these that presided over by Riegel is, perhaps, the most famous and has produced not only the largest harvest of practical results but the largest number also of distinguished investigators in the same field of research. Professor Riegel is a writer of no ordinary attainments: his powers of literary expression and of philosophic and logical reasoning place him in the front rank of medical authors of to-day, so that when we come to consider his unrivalled resources for the acquisition of knowledge on his special subject and his remarkable gift of literary exposition it is scarcely surprising that the great volume on the diseases of the stomach which he has contributed to Nothnagel's Encyclopædia is of the superlative degree of excellence which is universally admitted. It is greatly to be regretted that the failures and shortcomings of our own system of medical education make it impossible to produce teachers of the stamp and attainments of Professor Riegel and that our students and practitioners have to depend on the translation of foreign works for their sources of information. It was only recently that we reviewed in these columns a second edition of Professor Hemmeter's work on the same subject, a work which heretofore has occupied among us the position of the leading textbook on diseases of the stomach.

The duty of editing the translation of Professor Riegel's book has been entrusted to Professor Charles G. Stockton of the University of Buffalo and very excellently has the work been done. The literary brilliance of the original loses little of its polish in the English rendering and the few hiatuses in our knowledge which recent work has filled in and which the far-sightedness of the author did not anticipate have been dealt with by the translator in adequate notes and additions, all of which can be readily distinguished from the original text by the use of brackets. The subjects which have been thus amplified include a description of the following conditions: periodic vomiting in children, acute dilatation of the stomach, achylia gastrica, and congenital stenosis of the pylorus, to mention only the more important. The contents of the volume have been arranged in the following order: in the first part, which comprises the general diagnosis and treatment of gastric disease, the methods of examination both physical and chemical are described separately and systematically and at the expense of some 150 pages. Then follow the treatment of the diseases of the stomach in general and the treatment by drugs, by physical methods, and by surgery in particular. The second part, which occupies rather more than two-thirds of the pages of the entire volume, is devoted to the consideration of the special diseases of the stomach. Each group of symptoms which is to be regarded as a type or as a special disorder is arranged in an independent section; the order of arrangement as regards pathology, etiology, treatment, and other details is the same in each section. Each unitary section is completed by a very comprehensive bibliography.

Professor Riegel's book may be contrasted with Professor Hemmeter's work on the same subject in two respects. In the first place the latter author, as perhaps the leading authority on the physical methods of examination of the stomach, attaches more importance both for the purposes of diagnosis and of treatment to these expedients than does Professor Riegel who as a pioneer in the methods of chemical examination is naturally biased in their favour and loses no opportunity of infecting his readers with the same enthusiasm. In a second respect it may not perhaps be impertinent to contrast the two authors. While Professor Riegel's attitude of mind towards disease is one directed towards a process that of Professor Hemmeter is more of one which looks upon disease as a specific entity. Professor Riegel is not content with giving the disease a name: so far as possible he attempts to draw an accurate picture of the process which underlies it. This philosophic conception does not lend itself to a cut-and-dried method of classification and in the multiplication of possible pictures there is apt to be obscuration from the overlapping or superposition of images. The dangers which might arise from such a method of regarding disease might clearly prove fatal to a less skilful and brilliant exponent than Professor Riegel. However, by the occasional sacrifice of conventional classification he has emerged triumphant and by bringing his pictures into proper line and perspective he has produced a kaleidoscopic effect which shows clearly how one disease may merge insensibly into another without obscuring the central features which other authors accept as the *distinguishing* characteristic of specific entities.

It is, perhaps, open to question whether the author credits the nervous system with so important a rôle in the determination of gastric disease as indirect evidence and analogy warrant; for instance, in the pathogenesis of round ulcer of the stomach, the neurotrophic theory of Stockton hardly, in *our opinion, deserves to be dismissed summarily as* a theory which "throws no light on the subject." This theory suggests "that by the influence of some process analogous to herpes, to idiopathic hæmatoma auris, to Raynaud's disease, or to herpetic gangrene—some distinct and persevering nerve perturbation—we may best explain the recognised and unaccounted-for features of the clinical history" Professor Riegel was, we believe, the first observer to indicate the association of hyperchlorhydria and gastric ulcer, an association which is now almost universally admitted; in combination with Stockton's theory of gastric ulcer it certainly elucidates some obscure points in the etiology, such, for instance, as those of age and sex, which Professor Riegel seems unable to explain on his own hypothesis alone.

The weakest part, perhaps the only weak part, of this book is that which deals with dietetic treatment. This, especially when details of *menu* are entered into, is colourless and monotonous in the extreme. We could imagine that in many instances the dyspeptic patient would almost as soon submit to the inconvenience of his complaint as follow out the dietetic *régime* prescribed for him.

A Text-book of Chemistry for Students of Medicine, Pharmacy, and Dentistry. By EDWARD CURTIS HILL, M.S., M.D. Philadelphia: F. A. Davis and Co. 1903. Pp. 523. Price $3.

THIS work is evidently written by a writer of considerable teaching experience who is alive to the importance of a sound knowledge of theoretical and practical chemistry to the medical student. It is not often that teachers are able to recommend to the medical student a book which covers the many sections of chemistry which bear directly upon medical science. Usually any attempt to make a book so wide in scope produces far too bulky a volume and one altogether outside the limitations of a handbook. Dr. Curtis Hill has succeeded in this task and as far as possible without sacrifice of details, though the plan of the work necessarily involves brevity. He gains space, for example, by the use of symbols instead of writing out the names of the elements. This method leads to some curious writing at times. Thus under the heading of iodine occur such sentences as "I was discovered in 1811 by Courtois, a Parisian soap boiler." Throughout the work the spelling is according to the American method which leads to further abbreviation. As illustrating the comprehensiveness of treatment and the way in which the author has adapted the book to the needs of the student of medicine it may be stated that the work is divided into the following chapters: Medical Physics, Chemic Philosophy, Inorganic Chemistry, the Carbon Compounds, Analysis, Incompatibility, Sanitary Chemistry, Toxicology, Physiologic and Pathologic Chemistry, and Clinic Chemistry. That all these departments of chemical science have been dealt with in the limits of this volume without serious omissions is an achievement upon which the author may be congratulated. The student of medical and chemical science will find this book very helpful.

The [illegible] Teeth and Associated P[illegible] [illegible] C.S. L D.S. Eng., L.R.C.P. [illegible] London: Dental Manufacturing Company. Pp. 633. Price 25*s.* net.

IN many respects this book is unique inasmuch as it is the first time that a complete account of the histology and patho-histology of the teeth has been dealt with in one volume and in such an exhaustive manner. The contents are included under three headings, the first being the Histology of the Teeth and Associated Parts. In the initial chapter of this part Mr. Hopewell-Smith draws attention to what is a most important essential in the study of tissues under the microscope—namely, "careful preparation"—and he instances the discovery of the real nature and characteristics of Nasmyth's membrane as following on the employment of proper methods of preparation. A good idea of the character of the book may be gained from the chapter on enamel. The subject is considered under the following headings: General Characteristics, Enamel Rods and *Interprismatic Substances*, Curvatures of Rods, Supplemental Columns, Brown Striæ of Retzius, Lines of Schreger, and Enamel "Spindles." Each section is clearly described and well illustrated and the writings of different histologists are alluded to and their views are placed in a clear, straightforward way before the reader. In the chapter on the pulp we perhaps see the author at his best and we are treated to a most complete account of the histology of this tissue. There is evidence here of considerable original research into the structure of the odontoblasts at the different stages of life and also into the innervation of the pulp. The ultimate termination of the sensory nerves, as the author remarks, "constitutes one of those histological puzzles which yet remain unsolved." Considerable space is devoted to discussing the question and the views of different writers are marshalled in review, the author himself expressing the belief that the nerve fibres "terminate in a basket-work of varicose fibres, embracing and often closely attached to the cell walls of the individual odontoblasts."

Part II. is devoted to the Histogenesis of the Teeth of Mammals, Fishes, and Reptiles, and Part III. to the Pathohistology of the Teeth and Associated Parts. The opening chapters of the latter are devoted to the pathology of the enamel, and reference is made to a condition not hitherto described in text-books—namely, nanoid or dwarfed enamel. In this condition the crowns of the teeth may be fully developed but present rough lustreless surfaces of a somewhat light yellow colour. In the cases investigated enamel was always present but greatly attenuated and stunted in growth. We are hardly in agreement with the author on the histology of syphilitic teeth. He remarks: "The surface is not absolutely smooth but contains pits which are filled with micro-organisms of a reddish-brown colour, thus indicating that caries is not in progress." In many cases of congenital syphilis seen in practice with typical-shaped teeth the enamel is devoid of pits and is good in structure. The description of syphilitic teeth in text-books is frequently incorrect and misleading. In the chapter on pathological conditions of the dentine the description of dilaceration as a developmental disease is open to criticism. "Dilaceration" at the outset is a bad term and the condition is the result of injury to the growing tooth and is in no way due to a developmental defect of the dentine papilla. The illustration, too, given of a "dilaceration" of the radicular region of a human canine we are inclined to consider as simply showing a tortuous root the result of crowding and in no respect a developmental error. By these criticisms and others which might be offered we wish in no way to depreciate the value of a book which is a most excellent contribution to the literature of medical knowledge. The printing of the book is good but is it not possible for expensive books of this character to be better bound?

LIBRARY TABLE.

Gynæcological Nursing. By NETTA STEWART. Edinburgh: Oliver and Boyd. 1903. Pp. 174. Price 2*s.* 6*d.*—This little book contains an excellent account of all that a gynæcological nurse ought to know. There are many points in which such nursing differs from that met with in surgical wards, and on these due emphasis is laid in this work. The author has been fortunate in her efforts to give sufficient prominence to those facts which are of special importance and yet not to leave out anything of value. In a future edition we would suggest that Miss Stewart should avoid the use of such terms as Henry's lotion and she should be a little less dogmatic in regard to some methods of treatment such as the administration of vaginal douches after perineorrhaphy and the use of the catheter in similar cases, points upon which surgeons are by no means in entire agreement. An index would considerably increase the value of the book. It is, however, a manual which we can strongly recommend to those nurses who wish to know something of this special class of work.

A Simple Method of Water Analysis. By JOHN C. THRESH, M.D. Vict., D.Sc. Lond. Fourth edition. London: J. and A. Churchill. Pp. 62 Price 2*s.* 6*d.*—The demand for a fourth edition of this little manual is evidence of its usefulness. The method described is especially designed for the use of medical officers of health and is based, of course, upon laboratory methods which are usually carried out with some detail. The author has in response to the request of several medical officers of health added a description of a simple form of distillatory apparatus for the estimation of the free and organic ammonia Practically the same methods as are applied to the examination of a drinking water are applied also to the examination of sewage. Dr. Thresh's remarks on the significance of the results of analysis are admirable.

Matriculation Directory. September, 1903. London: University Tutorial Press, Limited.—This is a volume of the University Tutorial Series and will be found an excellent guide to anyone who intends to study for the examinations of the University of London. In addition to a University of London Calendar for 1903-04 directions are given as to the best course of study according to the nature of the degree which the student intends to take, suggestions are made with regard to suitable text-books, and the examination papers set for the last matriculation examination are printed, together with specimen solutions.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—The opening article in the November number is Professor D. J. Cunningham's introductory address delivered to the class of anatomy in the University of Edinburgh on Oct. 13th. It consists essentially of an interesting historical account of the growth of anatomical knowledge. Dr. A. Logan Turner of Edinburgh publishes a further instalment of his memoir on the Patho logy of "Bone Cysts" in the Accessory Sinuses of the Nose. Dr. Henry Barnes of Carlisle writes on the celebrated Boerhaave of Leyden. Dr. Thomas D. Luke of Edinburgh discusses the action, administration, and effects of ethyl chloride used as a general anæsthetic. His opinion is strongly in its favour.

Scottish Medical and Surgical Journal.—Insanity and Alcoholic Excess is the subject of the first article in the November number. The author, Mr. John Carswell of Glasgow, considers that "it is tolerably clear that inebriety as it has been revealed by the operation of the Inebriates Acts is a type of mental disorder as definite in its origin, course, and general characteristics as any other form of disease." Habitual inebriety, according to him, is not a stage in the causation of insanity but is a form of mental disorder which as the law at present stands rarely presents symptoms of certifiable insanity. There are also articles on the Occurrence of Epistaxis at the Onset of Acute Rheumatism, by Dr. H. G. Langwill of Leith; on Protargol in Ophthalmic Practice, by Dr. Angus McGillivray of Dundee; and on Abdominal Sections, by Dr. J. M. Munro Kerr of Glasgow. In a short note on the Abdominal Muscles in Relation to Hernia Mr. J. W. Dowden of Edinburgh remarks that in cases of lax and protuberant abdomen much improvement may be effected by systematically exercising the abdominal muscles.

Mercy and Truth.—In one of the articles contained in the November number Dr. D. W. Carr of Julfa in Persia mentions that at the mission hospital in that place local anæsthesia produced by cocaine was resorted to in 61 operations performed in 1902; the operations included 39 for the radical cure of hernia and one abdominal section.

Journal of the Royal Army Medical Corps.—The November issue of this journal contains a useful article from the pen of Colonel J. Edward Squire, R.A.M.C. (Volunteers), on the work of a Volunteer Unit of the Royal Army Medical Corps in Camp. This is a matter which, as the author points out, is beset with considerable difficulties and the plan detailed will be read with interest by all medical officers. The article is illustrated with a photoprint and plan of the Royal Army Medical Corps (Volunteers) Camp, London Companies, at Aldershot, 1903. Major C. E. Freeman, R.A.M.C., discusses for the benefit of officers and others proceeding on duty to Bermuda the geographical and other features of that colony. Hints on the kind of kit required are given and as many officers are married some points which may be useful to ladies are included in the article. The population of Bermuda consists, apart from the naval and military element, of 17,535 persons, of whom 6383 are white. Major Freeman concludes his interesting description of Bermuda by remarking that "there is much to attract anyone who is a lover of nature and the sea." Major W. H. Horrocks, R.A.M.C., has a long paper on the Bacillus Coli Communis as an Indication of Sewage Contamination of Water Supplies, and Lieutenant-Colonel S. F. Lougheed, C.M.G., R.A.M.C., some notes entitled "Further Cases of Perforating Gunshot Wound of the Skull."

South African Medical Record.—This colonial monthly journal is one of the most recent additions to the list of our contemporaries, having reached its eighth number in October. The original articles in this issue are on the Medical, Social, and Legal Aspects of Insanity, by Dr. T. D. Greenlees of Grahamstown Asylum; on Student Life 50 Years Ago, by Mr. F. Ensor of Port Elizabeth; and on Camp Fever, by Dr. J. E. Mackenzie of Kimberley. The leading article is on Hospital Scandals and their Lessons It seems that "at the present moment a very bitter disagreement between the matron and the nurses under her control is agitating the Johannesburg Hospital." The new Somerset Hospital appears also to have established a reputation for internal discord. The *Record* is edited by Dr. W. Darley-Hartley and published at Lloyd's Chambers, Long-street, Cape Town. The London agents are Messrs. Baillière, Tindall, and Cox, Henrietta-street, Strand, W.C.

The Journal of Physiology. Edited by Sir Michael Foster, K.C.B., F.R.S., and J. N. Langley, Sc.D., F.R.S. Vol. XXX., No. 2. London: C. J. Clay and Sons. Nov. 2nd, 1903. Price 8*s.*—The contents of this number are as follows: 1. The Paralysis of Nerve Cells and Nerve Endings with Special Reference to the Alkaloid Apocodeine, by W. E. Dixon, M.D. This alkaloid is shown to lower blood pressure, produces vaso-dilatation, causes the heart to beat more rapidly, increases the automatic movements of plain muscle, increases reflexes, paralyses the motor nerve endings in voluntary muscle, and very readily paralyses nerve cells in the same way as does nicotine. 2. A Method to Demonstrate the Changes in the Vascularity of the Submaxillary Gland on Stimulation of the Secretory Nerves, by R. Burton-Opitz, with two figures in the text. It is shown that stimulation of the chorda tympani incited a blood flow which was from 1·7 to 5·6 times greater than the normal. Stimulation of the sympathetic fibres, on the other hand, led to almost a complete stoppage of the blood flow. 3. The Nature of the Physiologically Active Substances in Extracts of Nervous Tissues and Blood, with some remarks on the Methods of Testing for Choline, by Swale Vincent, M.B., and W. Cramer, Ph.D. The experiments of these observers show that there are two groups of substances in watery extracts of nervous tissue which when injected into the veins lower the blood pressure. One group is easily soluble in absolute alcohol and the other is nearly insoluble. The alcoholic solution contains two depressor substances: one of them has its effect abolished by atropine and the other has not. They have not found any choline in brain substance. 4. Investigations on the Proteolytic Enzymes of the Spleen of the Ox, by S. G. Hedin. In this article two proteolytic enzymes are stated to be present in the spleen of the ox; both have been found in two forms—combined with nuclein substances and *not combined with nuclein substances.* The enzymes are probably contained in the leucocytes of the spleen. 5. Atropine and the Hyoscyamines—a Study of the Action of Optical Isomers, by Arthur R Cushny, M.D., with two figures in the text. The two substances are stated to act when pure in the same way and with equal potency on the central nervous system of the frog. Atropine possesses a more powerful stimulant action on the reflexes of the spinal cord in the frog than does hyoscyamine, but hyoscyamine is almost twice as powerful as atropine in its action on the nerve ends in the salivary glands, the heart, and the pupil 6. On the Presence of a Proteolytic Enzyme in the Normal Serum of the Ox, by S. G. Hedin. 7. Contributions to Our Knowledge of the Action of Enzymes, Part I., the Influence of Electrolytes on the Action of Amylolytic Ferments, by Sydney W. Cole. The number also contains the Proceedings of the Physiological Society.

Looking Back.

FROM

THE LANCET, *SATURDAY,* NOV. 12, 1825.

LECTURES ON THE ANATOMY, PHYSIOLOGY, AND DISEASES OF THE EYE.

By Mr. LAWRENCE.

London Ophthalmic Infirmary, Moorfields.

LECTURE III.[1]

Physiology of the Eye-ball.

A question here arises, how these changes[2] take place. They are not produced by the immediate influence of light upon the iris; for if we direct a strong light upon that part, taking care that it shall not enter the pupil, no contraction of the aperture takes place. The iris does not move; the pupil is not altered, unless the retina be influenced.

If then, the motions of the iris depend on the retina, when the latter becomes insensible to light the pupil ought no longer to exhibit any change from variation in the quantity of light, and any degree of insensibility in the retina ought to be accompanied with a corresponding deficiency of motion in the iris. In general this is the case; but the phenomena of disease present some circumstances which are not reconcileable with this view of the question. In the first place, we must distinguish between the independent motion of the iris, and its associated or sympathetic action. The latter often continues, when the former is at an end. Sometimes the optic nerve is completely insensible in one eye, and light produces no effect whatever upon the iris of the diseased eye, if the sound eye be kept carefully closed; but if you produce motion in the iris of the sound eye, by varying the quantity of light, corresponding motion will be observed in the diseased eye.

Another circumstance is quite irreconcileable with the opinion which regards the action of light upon the retina as necessary to the motions of the iris. In some instances, not merely of partial, but complete amaurosis, the iris not only retains a degree of motion, but occasionally its movements are perfect. In amaurosis caused by hydrocephalus, when the retina is completely insensible, so that the patient cannot distinguish light from dark, I have not unfrequently seen, and pointed out to pupils in this Infirmary, a perfect state of the motions of the iris. The phenomenon in question is not confined to instances of that description.

These facts throw considerable doubt upon the received notions respecting the physiology of the motions of the iris, and on the usual explanation of that familiar phenomenon, the changes in the dimensions of the pupil.

[2] *Contraction and dilatation of the pupil.*

DR. OTTO SCHMIDT'S SPECIFIC TREATMENT OF CANCER.

AN ADDRESS DELIVERED BEFORE THE ABERNETHIAN SOCIETY AT ST. BARTHOLOMEW'S HOSPITAL ON NOV. 5TH BY H. JOSSÉ JOHNSON, M.B. LOND., D P.H. CANTAB, FOLLOWED BY A DISCUSSION.

MR. PRESIDENT AND GENTLEMEN, — When less than three weeks ago I asked to be allowed to lay before the members of this society the notes of my observations on Dr. Otto Schmidt's specific treatment of cancer I hardly expected to have so early a date granted me as the present. This is, as you know, the evening set aside for your President, Mr. H. E. G. Boyle, to address you. He, however, most generously decided to postpone his paper in favour of the subject on which I am about to speak. I now at once beg to thank him for his most self-sacrificing action and to express the hope that my handling of the subject will not make him regret his generosity. I should also like to express the gratification I feel at being allowed in the first place to make my communication in my old hospital to St. Bartholomew's men. The Abernethian Society is an old friend. The first paper I ever perpetrated was read to its members many years ago. The subject then was the value of a knowledge of the German language for medical studies. My most recent experience has made me more sure than ever of the views I then held. It is just that knowledge and training which have enabled me in a comparatively short time to form a definite and settled opinion upon that question which is certainly the burning one in the medical world, the question which deals with the cause and successful treatment of cancer, or rather of the cancerous process. When it was proposed to me that I should go to Cologne and study under Dr. Schmidt and report upon the treatment which he was then initiating on the strength of a discovery he had made, you may easily understand I was most willing to go and considered myself very fortunate. My stay in Cologne was prolonged and as Dr. Schmidt put all facilities at my disposal as well as a great deal of his valuable time—he is in large practice as a consulting and operative surgeon —I think I may say I got a very thorough insight into the method and *rationale* of his treatment. What I saw and learnt I propose shortly to lay before you this evening.

There can be no useful purpose in discussing the various theories as to the causation of cancer here or now. The one most generally held amongst clinicians is the parasitic theory. It is upon this theory and the discovery by him of a parasite that Dr. Schmidt's treatment is based. It alone, therefore, need shortly be outlined. According to this theory the occurrence and growth of carcinoma and sarcoma are due to a living parasite, that is to say, a living parasite enters the body and there finds an anaplastic abnormal cell. Under suitable conditions the parasite irritates this cell to division and to produce new cells of its own kind. Into these new cells the progeny of the parasite enters and so the vicious circle is formed. The aggregations of cells, all of the same kind, form malignant growths, and wandering cells of the same kind carrying the parasite form metastatic deposits wherever they come to rest. The growths and metastatic deposits press upon, and destroy, the normal tissue of the organ in which they grow, but the prime cause of the growth, of the destruction of the normal tissue and of the eventual death of the sufferer is the parasite. The parasite is what we have first and foremost to combat and if possible to remove from or destroy in the body of the patient, for without the irritation, and this irritation constantly renewed, the anaplastic cell will not divide and increase. Unlimited growth of the tumour is only due to unlimited growth and multiplication of the parasite. That is, shortly, the parasitic theory. You will see that, according to this theory, any treatment to be successful must be anti-parasitic and not antitoxic, and therefore by some means anti-bodies must be introduced into the blood of the patient, that is, he must be actively immunised or else we must passively immunise him by injecting a serum containing anti-bodies ready formed, the serum of the immunised animal. This is the view held by Dr. Schmidt. He considered that the direction in which successful treatment must be sought was clearly marked out—namely, that a specific treatment was the only one. About the middle of last year (1902) after many years—nine or ten—of research, Dr. Schmidt succeeded in cultivating artificially a parasite hitherto unknown and at least more or less undescribed. It fulfilled most of the conditions necessary to prove its specificity. It was found in every malignant growth examined; it was capable of artificial cultivation in pure culture. In two cases—and I shall come to that point again —tumours were produced in white mice by injections of pure culture. Fourth, the same parasite was found in these tumours and from them was again cultivated in pure culture. Fifth, the parasite does not occur in benign tumours. As to point three, the difficulty of producing malignant growths in any animal is enormous if only pure cultures of the parasite are used. First, who can say which animals have the necessary anaplastic cells? And granting that such an animal were found we know that the parasite and the cell alone are not enough to cause the disease. In all these cases there is a third factor, which we may call environment. Yeast and sugar want the environment of warmth and moisture before the yeast can grow and the alcohol be formed. We all have lungs and we all have tubercle bacilli and pneumococci; but we do not all have phthisis and we do not all have pneumonia every day. It wants a certain environment besides. Given the anaplastic cells and the parasite, who can say what the environment of the animal must be in order that they may react and produce a malignant growth? Jensen's experiments quoted in the *Hospital* of Oct. 3rd by Mr. D'Arcy Power were not inoculations in the pure sense of the term, they were not inoculations of pure culture; they were implantations of growth—cells and parasite—and therefore they do not compare at all with the little white mice which were infected by the pure culture. Having settled these points to his satisfaction Dr. Schmidt felt compelled to commence the treatment of patients. I give it in his own words. He said to himself, "The most notable task of the physician is to cure If I have found something which promises to be of therapeutic value to patients suffering from a horrible disease and being convinced as to the correctness of my observations it becomes incumbent upon me to put my knowledge to practical use, even before science has allowed that it fulfils all her strictest requirements. No cancerous person was ever cured even by the most beautiful theory and if I wait till all authorities have given their opinions much time will be lost and much suffering left unrelieved."

It is not my intention now to enter minutely into the appearances of the parasite, its mode of growth, or the parts where it is most abundant. Such descriptions without diagrams and photographs are useless and I have none to show you. Suffice it to say that both in appearance and character the parasite is very varied Those who have studied the work of Russell in the *British Medical Journal* in 1890, or of Gaylord in the *American Journal of the Medical Sciences*, or the work of Schüller (1901) will know the various forms which the cancer parasite is capable of assuming. I have had the privilege of seeing all the forms which those authors describe and which are various forms of the parasite produced in pure culture. Plimmer found them in 1138 out of 1278 fresh malignant tumours which he examined. That by artificial cultivation it is possible by varying the conditions under which they are grown to produce these forms proves to my mind the correctness of Gaylord's observations. At what point he was led astray by a false analogy need not detain us now. That these are different forms or phases of the same parasite has been proved beyond question. Dr. Schmidt isolated one single parasitic cell and by artificial cultivation under varying conditions of light, air, moisture, and warmth, produced all the other forms from it. The *rationale* of treatment is twofold. Firstly, active immunisation—that is, by the injection of cultures, 14 to 21 days old, which have been first killed by the application of heat (65° C.); and, secondly, passive immunisation, by the injection of the serum of immunised animals, sheep and horses, into the subcutaneous tissues of the patient. I shall bring to your notice accounts of cases which have been treated by these methods, by each of them alone and by both in conjunction. The potency of the serum of the immunised animals has not yet been brought to its highest point. It is a procedure which takes time and is expensive The height of the grade of a serum depends largely upon the amount in bulk of the virulent culture which the animal can absorb. Ordinary injections contain a quantity of bacterial envelopes which are simply unnecessary ballast and retain much of the toxin. To overcome this difficulty attempts have been made to produce an extract of the cultures and so to lessen the bulk of the injection by increasing its concentration. Buchner's method was to rub the mixture to a fine paste with Kieselguhr and to pass it through a dense filtrating material under a pressure of 500 atmospheres. Professor Allen Macfayden on Sept. 23rd last at Cassel showed that the toxins can equally well be extracted from bacterial and other cells by first subjecting them to a very low temperature, —190° C., by means of fluid air. This renders the bacterial envelopes friable and their contents are set free. It will now be possible by using this extract to bring animals up to a higher grade of immunity and also more quickly than before he made his most interesting experiments.

Treatment.—It is usual to commence the treatment of the cancer patient in a very mild form. On the first day $\frac{1}{15}$th of a milligramme of the sterilised culture is given and on the second day one tenth, on the third day two-tenths, and on the fourth day one milligramme. But no hard-and-fast rule can be laid down. These doses are usually large enough to produce the characteristic reaction. The sterilised culture is used suspended in ½ per cent. solution of carbolic acid. The serum has to be used in quantities of *20 centigrammes but as the potency is increased the quantity* will be diminished. It is immaterial in what part of the body the injection is made so long as there is sufficient loose connective tissue. It is not adviseable to inject into or near the tumour itself.

Results of active immunisation—The most constant and most striking result of the injections into the body of the cancerous patient is a specific reaction in the tumour and infected parts. This specific reaction which I have observed and watched in a large number of cases I shall describe more minutely presently. Injections of the cultures into a healthy subject or into one suffering from any other disease produced no symptoms whatever beyond the pin-prick of the hypodermic needle. But if the cancerous process is in the body then the specific reaction is produced whenever there is any recuperative power in the blood of the patient. After the second or third injections and generally eight or ten hours afterwards there is a general sense of malaise. The temperature rises more or less; most often the evening temperature alone is raised but sometimes the morning temperature is also affected In a few cases the highest temperature is found in the early morning hours. The rise may occur suddenly or it may go up by daily increments to 102° F., then it falls to the normal in two or three days. The primary rise of reaction may go on in spite of the discontinuance of injections as soon as the temperature rises at all. Patients whose blood is already poisoned by toxins—cachectic patients—often do not react at all. Their blood, owing to the amount of toxins already present, is incapable of being roused to the manufacture of anti-bodies; should there be a reaction it is a sharp rise to 103° or 104°, ushered in with rigors. Local signs and symptoms are noticed about the same time as the first rise of temperature. The constant symptoms are, firstly, swelling of the tumour and of any metastatic deposits or infected glands; secondly, pain in the parts or increase of pain if such were previously present; and thirdly, tenderness of all affected parts. As you will see from this description the specific reaction is, in fact, an inflammatory process with all the attributes of such a process—redness, swelling heat, and pain. One or other of the attributes may be masked or wanting, according to the site of the trouble. Thus redness does not show itself where the skin is not involved but local rise of temperature is often demonstrable where deep-lying structures are affected. In enclosed primary tumours and metastatic growths pain or an increase of pain is noticed eight to 12 hours after the second or third injection. It is generally of an aching or boring character, or if the growth is on, or near, a large nerve trunk it is described as shooting or lancinating. The examining hand is often led by the pain indications to find metastatic glands and deposits where the most careful examination failed to detect them previously. All affected parts at the height of the reaction are so tender that we may speak of a high grade of local hyperæsthesia. If the skin is affected the pressure of the clothes is described as unbearable. The objective symptoms closely follow the commencement of pain. The deposits swell, both to feeling and to mensuration. The consistence becomes firmly elastic, especially in small and medium-sized tumours. Those with more or less of a capsule give almost a sense of fluctuation. Infiltrating forms feel softer than previously but not elastic. If the skin is infiltrated there is inflammatory œdema. All parts of the tumour do not show these changes equally. The younger the growth the more marked is the reaction. The oldest parts show least change, often none at all in the earlier stages. The limits which clinical examination had marked out as the confines of the growth are exceeded in all directions. There is frequently a zone of redness two or three centimetres broad ending in a sharply defined border all round. Sometimes these reactive changes run out in tongue-like processes or bring to notice a band of infiltration leading to infected glands. If the skin is involved in the process the latest attacked parts show reddening and œdematous infiltration. Sometimes redness extends into the neighbouring tissues when the reaction is very violent.

The activity *of the reaction varies very much in individuals* and diminishes as the patient becomes immune. As far as can be told at present closed carcinomata react more violently than do those which are free or consist of breaking-down cells. Cachectic patients react hardly at all, and when I say cachectic patients I mean those who are suffering from the cancerous cachexia properly so-called, not those who on account of œsophageal or gastric cancer are suffering from starvation cachexia. These last react freely and well. 29 *cases have been treated sufficiently completely for* conclusions to be drawn from them. Nine of these were of the uterus, eight of the breast, three of the ovary, two of the stomach, three of the tongue, two of the intestines, one of the mucous membrane of the cheek, and one of the thigh—a sarcoma of the femur. For diagnostic and other purposes over 140 single observations have been made and in all the 140 the reaction was positive. It was also positive in 28 out of the 29 that I have just mentioned. The exception often proves the rule and this one offers a most striking proof of the specificity of the reaction and the value of injection for diagnostic purposes. It was that of a lady, aged 73 years, who had been ill for 15 months. There was a history of a hard tumour in the abdomen and ascites. The diagnosis of inoperable carcinoma had been made. Paracentesis was performed for the first time in August, 1902, the second was performed in January, 1903, and the third in April. A few weeks after the third paracentesis and when the fluid had again begun to accumulate in the abdomen the patient came under Dr. Schmidt's treatment The state then found was in the abdomen: above the inguinal region there was a slightly moveable tumour of the size of a goose's egg. The abdomen exhibited a coarse wave of fluctuation. The limit of dulness showed this to be free fluid. The general state was bad: pain in the gastric region and great emaciation. On this finding the previous diagnosis of inoperable carcinoma was confirmed and injections of sterilised culture were commenced. Contrary to expectation there was no reaction, not even the faintest, although inside 14 days the quantity was raised to six centigrammes or six times the maximal dose Therefore Dr. Schmidt altered his diagnosis and gave his opinion that it was an innocent and not a malignant growth. He did not hesitate to operate and at the operation a large cyst of the right ovary was found which was everywhere adherent to the anterior abdominal wall from the sternum to the hypochondrium. On the inner side of this was a group of small and medium-sized daughter cysts. This group remaining tense when the main cyst collapsed on paracentesis formed the small fixed tumour. The adherent cyst walls—not the mother cyst shrunk on itself—gave, when partially filled, as found on examination, every sign of free fluid. It was possible to remove the tumour completely. It was innocent in character in every part and the patient left 16 days afterwards cured. She is now well and has put on one and a quarter stones in weight This was the exception. The remainder of the cases were, according to all clinical and frequently also microscopical evidence, undoubtedly malignant in character. The greater part were recurrences after one or more operations. Only one of the cases was sarcoma; the rest of the cases were carcinomata. I may say that this evening I shall only mention such cases as occurred externally. Carcinoma of the uterus, of the œsophagus, of the stomach, and so on react in exactly the same way but any *descriptions one gave of* them might easily be looked upon as pious self-deceptions. Therefore I have chosen cases only which I have seen and where the external signs were easily observed. To illustrate the similarity of reaction in the two main classes of malignant growths I shall quote first a case of carcinoma and then one of sarcoma for comparison with it merely for the sake of pointing out the reaction. Mrs. H., aged 52 years, declared that immediately after a blow on the right breast in November, 1897, she noticed a small lump which grew until Feb. 7th, 1898. It was diagnosed as carcinoma in von Bergmann's clinic, in Berlin, and the breast and axillary glands were removed. In July, 1898, a further operation for removal of the supra- and infra-clavicular glands was undertaken. In March, 1898, the patient got a blow on the right forehead and "a boil" formed, as it was called by the patient, which on healing left a knot of the size of a bean. This was held to be a sebaceous cyst when the operation in July was performed as well as in further operations in November, 1902, and February, 1903, for the removal of recurrences of original growth *in situ*. It had now grown to the size of a walnut and in June, 1903, when a sixth operation for removal of recurrence of original growth was performed it had attained the size of an orange. Bergmann himself now pronounced it to be a metastatic deposit and gave a very unfavourable prognosis if he should operate. The husband was informed that two months would see the end. The operation was declined and she came almost directly afterwards to Cologne. On July 1st the last operation wound was not yet closed; there was no local recurrence and no glandular affections were to be found. On the upper right forehead there was a smooth, hard, evenly-rounded swelling three and a half inches long sagitally, two and a half inches broad, and rising to a height of five centimetres—that is to say, two inches, above the surrounding scalp, measured vertically. The consistence was everywhere equally hard, like a fibroid. The colour of the skin over the tumour was natural. Further behind and to the left was another knot of the size of a broad-bean. The injections were commenced on July 30th. Although the temperature rose directly after the first injection the local reaction showed itself first on the fourth day. This is the temperature chart.

Date.	Amount of injection (gramme).	Mouth temperatures.		
		Morning.	Midday.	Evening.
June 29th, 1903.	—	—	—	98·4°
,, 30th, ,,	0·00002	—	—	98·9°
July 1st, ,,	0·00004	98·7°	—	99·2°
,, 2nd, ,,	0·0001	98·7°	99·1°	99·5°
,, 3rd, ,,	0·00015	98·2°	100·2°	100·0°
,, 4th, ,,	0·0002	98·4°	99·3°	99·2°
,, 5th, ,,	—	98·3°	98·4°	99·3°
,, 6th, ,,	—	97·6°	98·0°	98·6°

You will see the temperature was taken before the injections were made and it was perfectly normal. $\frac{2}{100}$ths of a milligramme were injected on the first day, $\frac{4}{100}$ths ot a milligramme were used on the second day, and on the evening of that day there was a slight rise of temperature and that rise continued gradually as the injections were raised. When they were discontinued the temperature fell again to the normal in two days. But the patient, who previously had little or no pain, had on this fourth day not a moment's peace. In the region of the breast and under the arm the pains were aching and drawing in character, and in the tumour itself and in the right side of the neck shooting and lancinating. On July 4th, when the height of the reaction was present, the measurements were about one centimetre larger in every dimension; the consistence of the tumour was sub-elastic, the lightest touch was extremely painful, and the skin over it was tense and very red, so that it looked like a red polished ball. The redness extended two fingers' breadth into the surrounding skin of the scalp and forehead in all directions. The smaller tumour was enlarged, red, and tender. The part of the scalp between the two was not altered in the least. In the supraclavicular region and lying on the nerve plexus was a soft flat gland of the size of a hazel-nut, very tender, and touching it produced lancinating pains in the arms. There was a second enlarged gland in the infraclavicular fossa. On the sixth day the reaction was finished and the pain had gone and the tumour began to decrease in size. Later, at the beginning of last month, Oct. 6th, the glands had become perfectly hard and the pain from their contraction, especially the one on the brachial plexus, became bad and constant and the patient begged that they should be removed by operation. This Dr. Schmidt undertook to do and I assisted him. It was done on Oct. 10th. Two of them were found to be only small, but very hard, masses of connective tissue bound firmly to the surrounding part by strong fibrous adhesions. The other was undergoing degeneration. I shall refer to this again later. When I saw the forehead tumour for the first time it was about one-third bigger than when I saw it for the last time on Friday, Oct. 30th. It had steadily decreased the whole time and the patient herself was perfectly well except for the pain in the arm. She was cheerful and putting on flesh and was going on as well as any patient could wish to. She has attained such a degree of immunity that seven centigrammes of the culture can be injected without any reaction taking place at all. Now, by contrasting the reaction in the two cases—that is to say, that case with the sarcoma—you will see practically no difference. She had been treated with the Roentgen rays, and disarticulation of the thigh had been proposed and refused. The tumour was on the front and inner side of the thigh extending longitudinally over the whole middle third of it. The circumference of the affected leg, taken over the tumour, was—above, 24 inches; middle, 22½ inches; and below, 19¾ inches. To make sure that future measurements should be taken at the same place lines were drawn by means of a tape on the skin with a stick of nitrate of silver. The treatment began on July 22nd, when $\frac{1}{100}$th of a milligramme of culture was injected. On account of the increased pain the dose could only be gradually increased and consequently only the very slight rise of temperature in this case must be probably ascribed to that cause. Her temperature never rose above 99·1° F., but nevertheless the curve of evening temperature showed very clearly how the temperature did rise during the injections, and then when they were discontinued it again fell to normal two days afterwards. The pain in the tumour was much increased and the local rise in temperature was very marked. Measurements were taken at the height of the reaction and they showed an increase of two centimetres in all three measurements. At the end of the sixth week of treatment they had gone back three centimetres, so that the sarcoma had decreased in six weeks instead of increasing. The local processes of reaction are not confined within the limits of examination. These limits frequently are over-stepped and you find glands and metastatic deposits which previously defied the most careful search. This can only be explained by supposing that every tissue reacts to the specific irritation. There is, further, a zone of inflammatory œdema which is referable to an immigration of quantities of leucocytes into the surrounding tissues. This is only an exaggeration of the process found in the parts around every cancerous growth. In the case of one gland which was excised—in the carcinoma case—this immigration was well marked in microscopical sections which were cut. The other two showed no cancer cells. This one showed in the centre a few remains of infiltrated cells undergoing fatty degeneration and pressed upon by the surrounding fibrous tissue. But all round the gland there was a zone of leucocytes showing that reaction was still going on. Complete certainty as to the process can only be obtained by microscopical examination of strips of tissue removed from the parts during the height of the reaction. We obtained such material whilst I was there; it is being hardened and will be cut shortly. I hope to make a further report upon this point. In open growths the local processes of reaction run a different course; the most striking points are the drying up of the secretion and the diminution of the purulent discharge. When on the surface and so exposed to the drying influence of the air a crust can be noted on the third or fourth day of injection. This scab is not only dried secretion but includes a superficial dead layer of tissue. An accumulation of fluid is formed beneath this and is cast off. A new scab forms, this is cast off like the other; and so the process continues until the healthy tissue is reached on which the scarring proper can take place. In body cavities and moist parts, such as the mouth, the corresponding tissue is cast off in gangrenous pieces. This was illustrated in a case of cancer of the tongue which was in a very advanced stage. Early in the disease no definite diagnosis was made and it was so far advanced when recognised that operation was impossible. The anterior part of the tongue and the frænum were largely infiltrated. The growth was covered with a whitish stinking secretion. The mouth was swabbed out with hydrogen peroxide and anæsthetising powders were given to allay the pain. On account of the swelling of the tongue the minute dose of $\frac{1}{200}$th part of a milligramme of culture was used and only very gradually raised to $\frac{1}{10}$th of a milligramme, which was the highest dose she has had up to now. There was a decided reaction and an undoubted healing tendency was observed. After a few days the slimy coating disappeared and pieces the size of a pea were cast off. A line of demarcation was visible between the healthy and the inflamed parts. The pieces were first blue-black and then greyish and then fell off. After 14 days' treatment there was no suspicion of foul odour in the breath or from the tongue and that without using any disinfectants. This casting-off of parts was only at the edges where the tissue was already profoundly affected. The compact parts of the tongue showed only redness and swelling. Having now described the reaction which takes place in cancerous growths when sterilised cultures of the parasite are injected I wish to draw your attention to the value of the reaction as a fresh proof. I have mentioned that this parasite is the primary cause of malignant growths. It is the interchangeable relationship between the two which, to my mind, furnishes this proof. If the injection of minimal doses of a culture into subcutaneous tissues of the cancerous patient, far from the seat of the tumour, causes an inflammatory reaction in the growth which extends to its remotest parts and in which every nodule and metastatic deposit and every infected gland take part, and if only malignant tissue answers to it (and malignant tissue always does and healthy tissue never does) then the injected material is specific for the cancerous process. Unless we deny the facts which lie at the foundation of all serum therapy we must accept the relationship between the parasite and the growth, and this interchangeable relationship can only be one of cause and effect; the injection and reaction of the parasite on the growth must be cause and effect.

The healing process.—The reaction, then, is of an inflammatory nature, confined to the cancerous parts, more or less acute according to the newness of the growth and the condition of the patient. It is of short duration, a few days only. A chronic state of inflammation can be induced by setting up reactions at short intervals or by raising the injections gradually but without pause. In this last procedure the local effects and the pain are less but the final result is the same. The inflammatory process is not enough in itself to cause retrogressive change in the growth or to check proliferation of the cancer cells. The immigration of leucocytes is necessary for the destruction of the parasite. The anti-bodies can only weaken the parasites. For their complete destruction alexins are necessary *in vitro* and the leucocytes *in vivo*. To be able to produce the inflammatory process in the very part we wish to attack is therefore most important. Dr. Lovell Drage pointed out the importance of leucocytosis in such cases when speaking at the British Medical Association meeting in Swansea last July, and he had previously published his experiences in trying the effect of injections of cinnamate of sodium in producing leucocytosis. In the treatment I am describing this leucocytosis is produced and exactly in the parts where it is wanted. The leucocytes finish what the anti-bodies have begun. By the injection of serum from immunised animals the anti-bodies are introduced ready formed. If used by itself there is no reaction of the same local kind as there is with the cultures. A few cases where the serum has been injected into the tumour itself while in a state of inflammatory reaction have yielded very good results.

Retrogressive changes.—Such tumours as have been arrested in growth very soon begin to degenerate. If the growth of the cancer at its edge be very sluggish it may, without any treatment at all, show cicatricial changes near the centre and we may sometimes speak of partial cicatrisation in its oldest parts. The specific treatment greatly hastens these changes by reactive inflammation. In contradistinction to the natural cicatrisation it is not the central parts which show change but the youngest parts at the periphery of the tumour and often in several places at the [illegible] an[illegible] of [illegible] is the process which nature uses when she acts for the removal of the foreign or dead tissues in our bodies. As the result of any inflammatory process for repair, scar tissue is formed and it is the same in this treatment—a mass of cancer cells is absorbed and scar tissue adequate to the tumour is formed in its place. These strands of connective tissue often give rise to displacement of neighbouring organs or tissues. They may press upon anything they are near and do produce at times unpleasant consequences. The following two cases exemplify this healing process and also the effects of scarring. I have taken two because they are specimens of another point. The first was treated by active immunisation (cultures) and the other by passive immunisation (serum) only. A woman, aged 52 years, noticed that in July, 1902, her left breast began to get larger and heavier. In October it began to get firmer also. In February, 1903, it was pronounced to be inoperable cancer. The state in April, 1903, was as follows: in the left breast was one large firm tumour, in which six or eight lumps could be distinguished. The skin was adherent to the tumour all over; the tumour was immoveable on the ribs. You will perceive that it was an encephaloid carcinoma and not a scirrhus—a soft and not a hard growth. I draw attention to this distinction because in some cases scirrhus has been known to undergo change into fibrous tissue, especially after ovariotomy; but such a change as that is not met with in an encephaloid tumour. But the same change was produced in the soft growth as is described as occurring in rare cases in the hard one. The circumference of the breast was 44 centimetres from above downwards and from left to right 24 centimetres. Reaction came after the eighth injection of two and a half milligrammes. It was only of a slight intensity. Later during the progress of the treatment very considerable reactions took place and were produced for observation purposes by raising the dose of injection. During the remaining time the chronic inflammatory state of the whole mass has been kept up. The whole skin was red, in parts patchy, and considerably œdematous. As far as the redness extended there was local rise of temperature. The pain in the breast in the first months was rather bad but never so violent that anything beyond cold compresses had to be used. In the third week changes took place which could be looked upon as healing processes. The gland decreased to a small nodule of connective tissue; the breast tumour lost its knobby look and was smaller. The breast was softening but not so much as to give a sense of fluctuation. The part of the breast which was hard was about four and a half inches broad; it became harder and smaller and at its lower part a deep sulcus was formed above the nipple. And now after six months the case looks as follows. Round the nipple is a small ring of hardness, certainly not more than the width of my finger. The nipple is retracted and drawn in by the connective tissue. I wished last Friday, Oct. 30th, which was the last time I saw her, [illegible] dimensions for comparison with those I gave pr[illegible] that the [illegible] breast was as flat with the surface of the rest of the skin as it was possible to be. The skin over it was deeply wrinkled and below was a strong band of connective tissue which extends from the sternum to the angle of the scapula. This fixes the wrinkled skin firmly to the chest wall. It has drawn the right breast across the middle line and hinders the movements of the left arm and movements of respiration. Bodily and mentally the condition of the patient is good; she has gained 17 pounds in weight and she resumed her occupation four months ago. The case was shown several times during the period of treatment at the meetings of the Cologne Gynæcological Society; for the last time on Oct. 21st, when I was present, and a large number of medical men were able to control and to observe the changes which took place. The second case is another example of the ill-effects of this scarring which takes place. It was a case of cancer of the uterus which had been removed. It was undoubtedly a case of epithelioma and there was recurrence along the left broad ligament. After the mass of the cancer had disappeared constipation set in and colotomy had to be performed in the left inguinal region. And although the patient did very well from the colotomy she suddenly developed uræmic symptoms a week ago. A post-mortem examination by an independent authority has been promised. The case shows the ill-effects of connective tissue contractions. This case, unlike the last, was treated by serum and not by cultures. But there is one point which is of comfort in these inconvenient cicatrisations and that is that when you have nothing but fibrous tissue to deal with surgical interference is comparatively easy, and very often a slight operation will relieve what could never have been touched if it had been cancer.

What can be considered as the relative value of active and passive immunisation processes? At present it is uncertain. The impression gained is that the injections of serum alone, if energetically carried out, are enough to inhibit the growth of the primary tumour and to prevent the formation of metastatic deposits only temporarily. The serum has the effect of improving the sufferer's general state, but it has the drawbacks of all serum injections, erythema, pain in the back, in the kidney region, although as yet albuminuria has not been noticed, such as occurs for instance after the injection of tetanus serum. The unit value of the serum will have to be much raised from what it is at present but this is merely a matter of time and the treatment is young. It is possible that more suitable animals than those used—sheep and horses—may be found The more nearly the animal is related in the animal kingdom to man the more perfect the serum will be, so perhaps later we shall use apes. Nor is the unit of potency of the serum settled because animals are not killed by the culture. They only have a rise of temperature, so the unit cannot be measured as in the case of diphtheria and other antitoxins. The excessive formation of fibrous tissue in the place of the growth gave rise to the idea in Dr. Schmidt's mind that it might be lessened by the injection together with the serum of the cytotoxin related to the growth. It would thus accelerate the retrogression of the tumour. For this purpose growths of various kinds had to be obtained, mashed up, and injected in suspension into animals. But here a difficulty arose. Dr. Schmidt's colleagues refused to let him have the growths removed by the knife and when I had feed the attendant to have a growth the operator threw it into the fire rather than that the attendant should have it and hand it to me. It was not until I applied to my friend Mr. D'Arcy Power that we could get any material at all. But he took great trouble to procure and to send it to Cologne and now I hope experiments will be possible. That cytotoxins unaided should have any effect upon the malignant process is very doubtful indeed but some such claim has been made. We must remember that all cytotoxins which have been active have been produced by fresh, living, functioning cells—spermotoxin, nephrolysin, and so on, will recall this to your minds. The cells of a malignant tumour which we are able to incorporate are for the most part more or less degenerate; only an infinitesimal number of the outposts or newer cell growth can be said to possess the amount of activity required. But as the specific cytotoxin induced by a cell depends upon its contents and not upon its form the best serum we could expect to produce would be one dissolving fat and colloid material. This might possibly be used for hastening the dissolution of the old and played-out cells, but it would have no effect on proliferating cells; at least, it is highly improbable. If any effect has been brought about I think it is due to the anti-bodies produced in the intermediate animal by some of the parasites being incorporated unintentionally with the suspended cells when they were introduced. There is one fundamental point which is not nearly sufficiently insisted upon when considering the treatment of cancer but which should always be kept steadily in mind and it is this, that two factors are necessary for the complete removal of any malignant growth; firstly, the arrest of the malignant process and, secondly, the removal of its effects—the tumour. Suppose the outward and visible signs are removed by the knife, by caustics, or what not, is it not our sad experience that some proliferating cells are left behind and that recurrence is the rule? We can never speak confidently of the cure, but if by any means the cancerous process can be stayed and its cause removed we can begin to talk of cure, and the tumour is no more a foreign body or an innocent growth. Nature alone will probably deal with it efficiently. These retrogressive changes take place as soon as the stimulus to fresh growth is withdrawn. Even the youngest and most active cells on the border lose their power of proliferation and cannot implant themselves elsewhere. We may say, then, that the arrest of the cancerous process plus the removal of the growth would be a cure of cancer. But it is by no means the cure of the individual case. This will depend upon the extent to which important or vital organs have been destroyed or infiltrated. When considering individual cases we have three factors. Probably the most practical use of this treatment will be as an immediate sequence to operation to destroy the remaining parasites and cells and to immunise the patients from further attacks. Its value for diagnostic purposes I have referred to. For the preventive immunisation of those predisposed by hereditary taint or those who are nervous it might also be used with advantage. Most cases of cancer partake of a chronic ailment and the period over which treatment must extend is necessarily protracted. The patient has much to bear and at times the patience of attendants is heavily taxed. The practitioner's best help is good nursing and in this respect we in England, and especially at St. Bartholomew's Hospital, are far before other countries. It is impossible that such changes as I have described should take place in the body of the patient without his general system and feelings being profoundly affected, but when the sufferer sees friendly, willing, and, above all, confident faces around him his trust and hope are strengthened and he gathers courage to bear the pains which are necessary for his successful treatment.

You will have noticed that I have been very careful to speak always of the treatment of the cancerous process and that I have never in connexion with Dr. Schmidt's name, or what I have described, referred to this treatment as a cure of cancer. That or any talk of cure must be left to the lapse of time which proves all things. Nevertheless, it does not seem too much to assume a favourable attitude when in most cases treated up to the present, and in every case where the reaction was satisfactory, it can be demonstrated after five or six months' treatment that the original growth and metastatic deposits which were clearly present have, to say the least, not increased; that no further deposits have formed; and that the general body-weight has increased and the general subjective state of the patient has improved. That the treatment has something to do with this arrest will, I think, be granted. To argue coincidence for an unbroken series of cases such as I have seen would be straying beyond the limits of probability. One thing is certain, the surgeon should remove every malignant growth and every metastatic deposit so long as the danger of the operation is not too great. On the other hand, Dr. Schmidt's experience when treating absolutely inoperable cases—and he has had no others—is so favourable that he would not hesitate to use it in all these seemingly hopeless cases. But you will agree that such are not ideal or even, so to speak, thankful cases for treatment. In the future I am convinced that the treatment will be employed as a prophylactic immunisation immediately after surgical operations for the removal of malignant growths and it is when it has stood the test of time that we shall be able to speak, confidently I hope, of a cure for cancer.

Mr. BOYLE, the President, said that the society should feel proud indeed that the discovery of that form of treatment for cancer, should it eventually prove successful, was made known for the first time in England before its members. In the name of the members he extended to Dr. Johnson the cordial thanks of the meeting. There were so many of the teaching and visiting staff present that it would be an impertinence of him to discuss the paper; he would leave it in more competent hands.

Mr. A. WILLETT said: When I received the courteous invitation of the society to be present to-night my sole intention was to come as a silent visitor and to learn. And even now I rise only because it seems essential that someone should just set the ball rolling. Your President has said justly that the bringing of this subject before the society is a historical fact and it is remarkable that this society should have had two historical events in its existence. It probably is known to but very few here that, I suppose some 50 years ago, perhaps longer, the late Sir James Paget came here and for the first time in the world demonstrated the presence of the parasite of trichinosis. I should not venture, of course, to come here to speak upon what I may call the merits of this most instructive paper. I am, as it were, an old hulk. You, gentlemen, I may liken to the torpedo catchers; you are keen and anxious to take advantage of anything and everything that may help you in the pursuit of your professional careers. If I had any feeling on the matter I might almost say it is one of jealousy. I happen to be President this year of the Royal Medical and Chirurgical Society, and therefore I should have been justly proud if this paper had been read before that society. But whilst I say that I yet say that Dr. Johnson would have had a very much smaller audience. There were one or two points that occurred to me in the course of this paper which made a very deep impression. The first was the statement that this serum will only react upon the cancerous patient. It may be injected, we are told, and it has been tested over and over again, upon healthy subjects without producing the least reaction. That, I venture to think, is perhaps the most notable feature of the whole subject. We therefore now have a test of whether or not a patient is suffering from malignant disease. One other point, which was only just incidentally mentioned at the close of the address, also occurred to me—namely, why should not the surgeon as soon as he has removed a growth and found it to be cancerous proceed at once with this treatment? Another point is—and I would like to ask Dr. Johnson his views upon it—namely, why this serum should not be introduced before the patient is operated upon. All surgeons know how almost impossible it is to be sure of the extent and limits of any cancer. As Dr. Johnson himself said, one of the peculiar features of this serum injection is that all tissues which are infected at once [illegible] Well, we often [illegible] o whether in [illegible] ie disease; if [illegible] before the operation where and to what extent the tissues have become *either locally infiltrated or the disease has become disseminated* I think it would be of immense surgical and clinical importance. It was only that others who are much more capable of speaking on the subject should not delay that I ventured to say a few words in opening the discussion.

Dr. LOVELL DRAGE said: I was very much interested in one of the last remarks which Mr. Willett made. I have not been treating cancer on the lines of Dr. Schmidt but I have been working on the treatment of cancer by trying to determine the different therapeutic values of the compounds connected with cinnamic acid and cinnamate of sodium. A patient operated upon nearly three years ago was kept under treatment one month before the operation and for two months afterwards. Of course, it is yet early days to talk about recurrence but I may say I did no Halstead's operation. I simply removed the breast after the manner I had been taught by Sir Thomas Smith many years ago—simple removal. I could feel no glands certainly. The patient remains at the present moment absolutely well. She has put on flesh and she is able, and has been able, to carry out her duties ever since I operated upon her three years ago. She was laid up for three weeks. I have progressed materially since those days. As the gentleman who read the paper stated, I have been at work lately during the last eight months injecting solutions of cinnamate of sodium and I have obtained results very similar to those which you have heard to-night, only I have no German clinic and no help such as Germany provides for its workers. I have to trust to the more natural methods of observation and what I can do in a casual way. I have been very much interested, naturally, by the paper, and it is very curious how very much the reaction of this serum corresponds with the reactions of the latest solution I have been using. It is a weird chemical production, but I may say roughly that it is cinnamic acid with an alteration in the arrangement of the molecules of the substance. Organic chemists know very well that you may have exactly the same number of molecules in an organic substance and that by altering the arrangement of the molecules you get different therapeutic reactions. Since the meeting of the British Medical Association at Swansea I have elicited the sympathy and coöperation of our friend Dr. Lewis Jones and we have obtained some very remarkable reactions. We have had two patients whom he has kept under the x rays for five months and I have since been treating them. The reactions produced by my solution have been practically the same as those produced by the serum of Dr. Otto Schmidt. In fact, I should say that in one case—and I think Dr. Lewis Jones will support me—the reactions were even more violent and the inhibition of the growth was more rapid. I only mention these facts to stimulate, if possible, a little wholesome spirit of inquiry amongst the members here present. It is impossible for me to carry out the work quickly with the means at my command. Chemists working at the strictly chemical part of the business can work more quickly than I can; it is impossible for me to get the pharmacology worked out quickly, and I cannot experiment upon human subjects with bodies the dose of which I have to find out. The serum is a very definite thing; you cannot vary it very much; but these organic compounds, so far as my observation goes, we can vary to a very great extent, if not to an unlimited one, and with each variation in the composition of the body used we get a different therapeutic value. And if the cure of cancer is to be with this country as an honour I am sure it will depend upon getting the whole of the series of compounds connected with cinnamic acid thoroughly worked out from a pharmacological point of view. I am sure Dr. Lewis Jones will support and amply justify the truth of what I have said. I have always been firmly convinced from the results I have obtained that the early primary growths are most amenable. A great many growths if not actually removed are very much circumscribed in their activity. The question is, how you gentlemen are going to promote the inquiry. I believe anyone with any spirit of scientific enthusiasm can work at the subject in one way or another. The chemist can examine his compounds and the gentleman who has any cancers to treat can test the substance which the chemists and pharmacologists put into his hands. I am sure that in addressing a multitude of young minds there will be no practical opposition to anything new. One thing I have always felt in referring to this subject is that there is a wall of opposition, based upon a hopeless feeling of tradition, that because a thing is new therefore it *cannot be tried until it is certain it will do some good.* I can assure you, gentlemen, that even if the treatment of these growths does not add to the cure the relief in the symptoms which you can get for the patients will well repay your attention to its study.

Dr. F. W. ANDREWES (pathologist to St. Bartholomew's Hospital) said: I should like to express my own thanks for the paper which Dr Johnson has read. I have known him a good many years and I know him too well to doubt his own complete *bona fides* in the matter. *He is naturally in a* very much better position to judge of the effect of this serum upon the cases which he has seen and followed than we can be. At the same time I think it is only right we should sound a note of caution when we remember how often cancer parasites have been found. When one remembers Koch's tuberculin one cannot help [illegible] so very cautiously indeed in these [illegible] points which seem to me to be [illegible] views which Dr. Johnson has put forward and I would ask one or two questions about points which he passed over too lightly in my judgment. First of all he has not told us enough about this parasite; he has not told us of the class of organism it is; he has not told us how it is cultivated or what it looks like in culture. All these are points I should have been glad to have had information about. Neither has he told us the precise mode of inoculation of the horses or sheep—at least, if he did I did not catch it. Is it intraperitoneal or intravenous? So there are several points I should wish information about. But I agree with what fell from Mr. Willett, that if there is anything in this the most striking proof of it is the apparently specific reaction that arises when the cancerous patient is injected with these particular cultures I feel that one is not in a position to discuss this paper at all; the thing must stand or fall entirely on the ultimate fate of these cases, and that cannot be known for a long while yet. I feel it is rather early in the day to have said quite so much about it as Dr. Johnson has said.

Dr. JOHNSON, in reply, said: I will begin with Dr. Andrewes. There must be beginners somewhere. I want to begin; Dr. Drage wants to begin. We are trying to arouse a certain amount of enthusiasm. I came to St. Bartholomew's with my paper and not to the Royal Medical and Chirurgical Society because I wished if possible to interest the members of the staff here, to allow me to demonstrate that very reaction in the wards and in suitable cases of which I have sketched the theories here *this evening. As Dr. Andrewes* very properly says, the reaction of the injection of these minute doses into the subcutaneous tissues of patients far away from the tumour is exceedingly important and it is one of the great proofs, one of the earliest proofs, one of the only proofs that one can bring to bear without the lapse of time. With regard to the inoculation of the animals, I worked amongst Dr. Schmidt's animals, I saw his patients with him, and did everything with him from beginning *to end. The inoculation of animals is* subcutaneous always and not intraperitoneal or intravenous. Some intravenous inoculations have been made and probably that will be the way in which it will be carried out in future. For the reason I have mentioned before, that the parasite does not kill, we are able to inject fairly large quantities directly into the veins. It has been complained that I have not said more about the parasite. Well, I am not good at word-pictures and I have no real pictures to show you. I have seen them but I have no drawings. But if you wish to know what they look like you have them set forth in pictures in Schüller's book, and by Russell in his toxin bodies, and they are described beautifully in the *American Journal of the Medical Sciences* which I quoted. Then there is the organism that Plimmer described—that is to say, the cancer parasite in a certain form. The only difference in these cases is the one which I noted previously. Dr. Andrewes said he must sound a note of caution when we remember the number of cancer parasites which have been found. It is perfectly true many have been found and described, but may they not be all one? I do not know that there is anything to answer in what Dr. Lovell Drage said, except that he said he had not that State help which Dr. Schmidt had.

Dr. LOVELL DRAGE: Not State help, but that I had not a clinic and such help as the Germans have.

Dr. JOHNSON (resuming): Dr. Schmidt is in private practice and has to support his investigations out of his own pocket and he has done it. Mr. Willett asked as to injections before operation. Certainly they can be carried out, but the injection would introduce a form of inflammation which would render the operation much more difficult. Where the cancer process has made strides it would be far better that surgical interference should be called in than that nature should be allowed to contract and to leave a scar in surrounding tissues.

Gentlemen, I have to thank you very much for your kind attention and I hope I shall have the chance of showing you practically what I have sketched in theory this evening.

MEDICINE AND THE LAW.

The Diagnosis and Notification of Small-pox.

ON Nov. 3rd Mr. J. M. Wheler, a medical man in practice at Battersea, appeared at the South-Western police-court in answer to a summons for failing to notify a case of small-pox. There was no doubt as to the fact that a case of small-pox had been treated by Mr. Wheler as chicken-pox and that in consequence of this mistake other persons had become infected, but considerable question arose as to whether the defendant was aware of the nature of the disease to such an extent as to render him liable to conviction. It was suggested by the Battersea Borough Council, acting as the prosecutors, that as Mr. Wheler apparently felt some doubt in the matter he should have "taken advantage of the expert provided"—namely, the medical officer of health of the district—and that by failing to exercise all reasonable skill he was guilty of negligence. Mr. Garrett, the magistrate who heard the case, differed from this view and refused to accept the contention that Mr. Wheler, because he might have felt a doubt, should have therefore notified the case as one of small-pox, pointing out that if a medical man acting upon suspicion caused the removal of a man suffering from chicken-pox to a small-pox hospital the consequences would be very serious. He held that a medical man could not be expected to do more than to act to the best of his judgment and, acquitting the defendant of all negligence, he dismissed the case. The suggestion that the medical officer of health is provided as an expert whom medical men can consult in cases of doubt where dangerous infectious disease is suspected is clearly wrong. This is not the legal position of the medical officer of health and so long as his duties remain what they now are any assistance that he may afford in this way must be purely voluntary. To compel his attention and to obtain his opinion by notifying a case which may turn out not to be one of the disease suspected is a course which any medical man would properly hesitate to take. The question of how far a medical officer of health should render assistance upon such occasions was gone into at some length in THE LANCET of Oct. 12th, 1901, p. 987, the occasion being the publication of some correspondence which had taken place between a medical man and a medical officer of health upon this very subject. In the course of that correspondence the latter wrote: "I am always pleased to assist my medical *confrères*, but you must understand that the diagnosis of cases is no part of the duty of a medical officer of health. The responsibility of diagnosis rests with the medical attendant entirely." This, we think, is a correct statement of the position. Whether some method should be devised to enable a medical practitioner to obtain the opinion of one more experienced than himself in the case of such a disease as small-pox is another matter. The power to do this would be a source of protection both to him and to the public. At present with regard to his poorer patients who cannot afford to pay for a second opinion the medical man has to bear the responsibility himself, being only able to strengthen his own opinion by invoking the assistance of a friend, should he be able to do so. Mr. Wheler was successfully defended in this case by the London and Counties Medical Protection Society, Limited.

The Evidence of Medical Witnesses: Scene between Judge and Counsel.

A sharp difference of opinion occurred at the Lancaster Assizes at a late hour on Friday evening, Nov. 6th, between Mr. Justice Ridley and Mr. Sharp, counsel for a prisoner named Joseph Fleming, charged with a rape on a married woman at Barrow. Dr. W. A. Holmes of Barrow, who was called for the prosecution, stated in answer to the prisoner's counsel that he examined the prisoner and his clothing some hours after the alleged offence but that he found no marks whatever corroborative of the prosecutrix's story (who had stated that she was menstruating when the assault took place). Dr. Holmes added that he expected that a man in the prisoner's position would have removed any marks and have cleaned himself in the interval. Mr. Sharp made no remark as to this addendum by the witness during his examination, but when he commenced his address to the jury he animadverted upon it in a severe way. "No more scandalous remark was ever made by a doctor," he said. "Instead of answering the question put to him in the affirmative or negative, he made an addition he should not have done." Mr. Justice Ridley (sharply): "I do not agree with you, Mr. Sharp, that it was a scandalous remark on the part of the doctor." Mr. Sharp: "And I respectfully beg to disagree with you, my lord. I have heard the medical profession belauded, and rightly so, in this court, because of the way in which members of the profession give their evidence and I have generally found in my experience that they give their evidence fairly, but in this case I hold to my opinion that it was a scandalous remark for Dr. Holmes to make." Subsequently, when his lordship was summing up the case to the jury, he observed: "Now, I must say a word about the doctor. I disagree with the learned counsel for the defence in the observation he made. I think what the doctor did was not scandalous. He gave his evidence very fairly. Most members of the medical profession do give evidence fairly and properly, and I hope it will be made known that I think so, because if such an attack is made upon a gentleman in Dr. Holmes's position it is well he should be defended from such an uncalled-for attack. I never heard a more uncalled-for attack upon a professional witness. At any rate, if Dr. Holmes is to be attacked by one person in the court he shall be defended by another." The jury found the prisoner guilty of an indecent assault "under extenuating circumstances" and he was sentenced to four months' imprsionment. Counsel for the defence in a criminal trial sometimes resorts to an attack upon a witness for the prosecution in the endeavour to secure the acquittal of his client by diverting the jury's attention from the true issue. In the case above quoted the learned judge took care, as a judge should do, that the issue should not be so obscured.

MEDICAL MAYORS.—The following members of the medical profession have been elected mayors of their respective boroughs: Mr. S. J. Allden, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng. (Bridport); Mr. E. C. Andrews, M.D. Cantab., M.R.C.S. Eng. (Hampstead); Mr. W. Banks, M.B. Lond., M.R.C.S. Eng. (Falmouth); Mr. J. Campbell-Macaulay, M.R.C.S. Eng., L.S.A. (Honiton); Mr. J. H. C. Dalton, M.D., D.P.H. Cantab. (Cambridge); Mr. E. W. Kerr, M.D., M.Ch. Dubl. (Dorchester); Mr. David Lloyd, M.B., M.S. Glasg. (Denbigh); Mr. R. B. Searle, L.R.C.P. Lond., M.R.C.S. Eng. (Dartmouth); Mr. J. Soutter, L.R.C.P. Lond., M.R.C.S. Eng. (Hedon); Mr. H. Stear, M.R.C.S. Eng., L.S.A. (Saffron Walden).

THE LANCET.

LONDON: SATURDAY, NOVEMBER 14, 1903.

A New Serum for the Treatment of Cancer.

BECAUSE of the importance of carefully considering every method which may appear to afford the least possibility of success in the treatment of malignant disease and because of the somewhat loud advertisement which has been given by the daily press to the latest "cancer cure," we have thought well to publish in THE LANCET a full report of the Address on Dr. OTTO SCHMIDT'S Specific Treatment of Cancer which was delivered by Dr. H. JOSSE JOHNSON before the Abernethian Society of St. Bartholomew's Hospital, together with an abstract of the discussion which followed thereon. In his address Dr. JOHNSON deals with two aspects of the matter under consideration; first he refers to Dr. SCHMIDT'S view as to the causation of carcinoma and sarcoma, and next he describes a method of treatment which was suggested to Dr. SCHMIDT by the alleged discovery of a parasite which, it is claimed, can be found in every case of carcinoma and sarcoma and which has been isolated in pure culture from cases of both forms of malignant disease. And we may say at once that before Dr. SCHMIDT'S theory as to the exact causation of malignant disease can be accepted by the medical profession it will be necessary for very much more evidence to be produced. It is stated that Dr. SCHMIDT has isolated the parasite in pure culture and that he has produced tumours in two white mice by the injection of such cultures. But as to the exact nature of the parasite, or as to the kind of tumour which was produced by the injection, nothing which is in any way relevant is said. It is stated that Dr. SCHMIDT has isolated a parasite which, in one or other phase of its existence, corresponds with the various "cancer parasites" which have been described by writers on the subject from the date of RUSSELL'S "Address on a Characteristic Organism of Cancer" in 1890 down to the publication of SCHULLER'S Monograph in 1901. Dr. SCHMIDT'S description of a parasite may be, in a sense, comprehensive, but it is wanting in many details of proof which will be required by the pathologist before the validity of any claim to be the discoverer of the cause of cancer can be seriously considered. On one important point in connexion with this aspect of the matter Dr. JOHNSON is, we think, under a misapprehension; he stated in his reply to the discussion which followed on his address: "Dr. ANDREWES said he must sound a note of caution when we remember the number of cancer parasites which have been found. It is perfectly true that they have been found, but they are all one. No one has ever cultivated them before; that is the point. This man has cultivated them for the first time." The actual fact of the matter, of course, is that a considerable number of writers claim to have isolated and cultivated the *several* "cancer parasites" which they have described, and as examples we might mention SANFELICE, RONCALI, MONSERRAT, PLIMMER, LEOPOLD, AIEVOLI, KAHANE, WLAEFF, GAYLORD, SCHULLER, and VON LEYDEN.

However, it may be conceded that exact proof as to causation is immaterial if only Dr. SCHMIDT can show that he has in truth discovered the long-sought for cure for one of the most distressing of all diseases. His treatment must at the present moment be judged by its empirical results irrespectively of any scientific foundation which it may have in the alleged discovery of the specific parasite. Dr. JOHNSON gives us to understand that the new treatment for cancer comprises two methods, first, the production of an active immunity against the disease by the inoculation of the patient with a "vaccine" which is obtained by sterilising a culture of the parasite; and, second, the production of a passive immunity by inoculating the patient with the serum of a horse or a sheep which has been rendered actively immune by the first method. The injection of the "vaccine" into a patient with cancer is stated to be followed by a specific reaction which includes a rise of the body temperature and a local reaction in the primary new growth and in any metastatic formations in the glands or elsewhere; and in addition there are curative effects described. The treatment by serum injection is spoken of in perhaps rather less favourable terms It will be seen that, quite apart from any curative use, a most important value in diagnosis is claimed for the "vaccine," for we are told that although patients with the "cancerous cachexia" very often will not react to the "vaccine" we have now a method by means of which innocent growths can be with certainty diagnosed from malignant ones and by means of which the existence of metastatic deposits can be detected. In hesitating to accept without more definite evidence the claims which are put forward on behalf of this new treatment of cancer one thing justifies all precaution apart from other and grave sources of uncertainty. It is impossible to forget that quite similar claims have been urged on behalf of other "cancer cures" and have, on being tested, proved fallacious. Thus, WLAEFF obtained a "cancer serum" by inoculating asses with yeast parasites which had been obtained from cases of carcinoma and which were stated to produce malignant growth when inoculated into experimental animals. WLAEFF'S serum, it was stated, was used for the treatment of 40 patients with malignant disease, and in nearly every case a local reaction both at the site of injection and in the tumour itself was observed. But, in spite of this, WLAEFF has not been able to convince other pathologists of the value of his discovery. Dr. LOVELL DRAGE, who took part in the discussion at the Abernethian Society, was also struck by the similarity of the reactions which follow the injection of the cinnamic acid compounds, which he has been using for the treatment of cancer, with the reactions which Dr. SCHMIDT has obtained. Dr. DRAGE'S observations have appeared in our columns.

At the conclusion of his Address Dr. JOHNSON very properly indicated that he had been speaking of a "method of treatment" and not of a "cure." Before the word "cure" can be used much that is at present uncertain will have to be established clearly, and we understand that

Dr. SCHMIDT is pledged to give full details of the discovery which he claims to have made at a meeting of the Comitié für Krebsforschung before the end of the year. It is also understood that at the present time there is no supply of either "vaccine" or serum available for use in this country, and that consequently patients who may wish to undergo the treatment must proceed to Cologne and place themselves under Dr. SCHMIDT'S care. This course under present conditions, and until considerably more detailed information has been given, is not one which we feel justified in advising our readers to recommend. Further, we cannot but regret the premature publicity which has been given to the treatment as a "cure" in the pages of the daily press. Almost monthly the discovery of new "cancer cures" is made known to the public when the announcement has too frequently no better foundation than the elaborate ingenuity of a newspaper man in search of a sensational heading for the next day's issue. The inevitable result of these announcements is that patients with inoperable cancer turn with eager hope to that which they are assured will relieve their pain and suffering, only to meet with disappointment and to suffer, if possible, a deepening of their despair. Surely the most elementary ideas of humanity would suggest that the sale of a few extra copies of a journal is but a poor set-off to the aggregate of sorrow and disappointment caused to those who have already sufficient evil to endure. Every observation bearing on the cause or on the treatment of malignant disease is keenly watched for by the medical profession, not only in this country but throughout the civilised world, and every rational theory propounded on the subject is carefully weighed and examined; no good service therefore can possibly be rendered by the sensational publication in popular journals of the details of "cures" which have, so far as can be judged, no claim whatever to be regarded as such. That Dr. SCHMIDT'S treatment may prove to be the long expected cure for cancer is hoped for by none more sincerely than by ourselves. But until fuller information is afforded we are not able to express any favourable opinion on the subject

◆

Private Nursing Homes.

IN a recent issue[1] a correspondent urged the need of organisation of the medical and surgical nursing homes in this country and to point the moral he drew an unfavourable picture of the difference between the arrangements in English health resorts and in those of a small Swiss bathing town. One of the chief sources of complaint lay in the preposterous charges of English nursing homes which would seem to show that in England only the wealthy must be sick. That there is a large degree of truth in this complaint is evident to all practitioners who have endeavoured to arrange for the needs of middle-class or comparatively poor patients who are scarcely fit subjects for treatment in general hospitals and yet cannot cope with the expense of a nursing home without unduly crippling their resources. The fees in nursing homes are necessarily a matter of private arrangement. Those who cannot pay them need not enter, since broadly the cost is fairly set forth when the preliminary inquiries are made. There may be extras for operation fee, for medicines, for dressings, for washing, and for stimulants if required and these may amount to more than was anticipated, but the terms generally are dependent upon the nature of the nursing required and upon the room occupied. These in turn vary to some extent with the locality of the nursing home and in one sense it is to be deplored that nursing homes must almost inevitably be in the immediate neighbourhood of the medical quarter, where rents and rates are extremely high and where it is not always possible to insure quiet.

With few exceptions the nursing homes in London are commercial undertakings which must pay their way, and owing to the uncertainty of work the fees charged must be calculated so as to give a fair return for the original outlay, for the current expenses, and for the risk of many of the rooms remaining unoccupied during a large part of the year. It is often assumed that a large staff of trained nurses must continually be kept upon the premises, either actively engaged or ready for any sudden rush of work, and this furnishes further excuse for keeping up the high cost to the patients To those with intimate knowledge of the working of nursing homes this plea scarcely seems justifiable. In most homes the matron is herself a trained nurse who is able to undertake a certain share of nursing duties, and whether she assists at an operation or not she is generally present, directing, supervising, and receiving instructions, complaints, or other remarks with the urbanity acquired by long habit and holding herself responsible for any shortcomings. The number of nurses attached to the home varies with the number of patients and with the size of the home. Some are permanently engaged, others come and go as the rooms fill and empty, and this fluctuation, of which the medical men visiting the house may scarcely be conscious since they always see the familiar faces, is often necessitated by the value of space being so great that many of the nurses must sleep out and may therefore come from one of the neighbouring institutions for nurses. In this way the expenses of the nursing home are legitimately decreased, since there is no advantage in attempting to keep on the permanent staff greater numbers than are actually required for the average service of the home and there is a distinct objection to a large unemployed staff, since it must sometimes be difficult to maintain the discipline and quiet required equally whether patients are many or few.

Apart from these expenses it is often urged that the dietary ordered involves a large outlay, but expensive delicacies are surely very rarely demanded and, as our correspondent points out, the directions are not always implicitly followed. *Freshly* minced meat may not make its appearance with sufficient frequency and recooked mutton may sometimes be served instead of fresh mutton Although these difficulties are obviously of frequent occurrence in every household, in a nursing home where urgent cases demand excessive care some means should surely be found to overcome them. The question is whether greater organisation would produce more satisfactory results.

---

[1] THE LANCET, Oct. 31st, p. 1253.

At present we believe that in spite of what our correspondent terms the "preposterous prices charged" there are comparatively few nursing homes which yield preposterous profits; in many there is a constant struggle to meet expenses owing to the serious fluctuations of work, and in this struggle many well-trained ladies have lost their capital and have become hopelessly burdened with debt. Greater organisation might provide a few larger institutions in place of many small private nursing homes, but unless these could be established in the immediate vicinity of the medical quarter resident medical officers would be required in addition to the large staff of nurses and the cost of maintenance would be proportionately increased. Admirable equipment will not fill the wards or private rooms and it is possible that long periods of comparative inactivity would have to be faced, as in the fever hospitals where so often there seems to be no middle course between the strain of an epidemic and the intervening torpor. This uncertainty of work is felt greatly by all nursing homes, but the dependence upon the goodwill or caprice of a few supporters probably tends towards efficiency, though it cannot safely reduce the charges which must be based upon broad calculations of the average expenses.

There are already many semi-charitable institutions where patients are received upon what may be regarded as nominal payments, but in most of these there are regulations which, though well intentioned, serve to hinder many from claiming the benefits they offer. A comparatively poor patient may prefer to pay a comparatively small fee to his medical attendant and to retain his services rather than to be forced to employ a stranger attached to the institution who is, under the regulations, ready to offer gratuitous assistance; and it scarcely seems reasonable that there should be close scrutiny of the extent of the charitable reduction made by any member of the profession in any particular case, still less that it should be assumed that if there is any payment to the medical attendant the scale of charges in the home must be increased. Patients often shrink from the full disclosure of their means involved in the application form of some semi-charitable nursing homes, and the sad fact remains that for a very large number of patients there is in this great city no adequate provision in time of sickness. Admission to a general hospital proves unsatisfactory on many grounds; there is the question of hospital abuse, while, even if it were desirable to organise any regular systems of payment, there would still remain the difficulty of deciding what sum would be an adequate payment. Services which the majority receive gratuitously and for which the charge in most nursing homes is so costly as to be prohibitive would have to receive a price.

The foregoing remarks apply purely to medical and surgical homes and do not touch those receiving maternity and chronic cases, in which the conditions are so widely different that they merit separate consideration. We are not suggesting that the arrangements in vogue for establishments of either of these classes should be altered; they exist to meet well-defined wants and, in our opinion, justify their existence. This, we believe, is the opinion also of the whole medical profession.

The Operation upon the German Emperor.

THE following authorised announcement has appeared in the English and continental press :—

> His Majesty the EMPEROR to-day underwent an operation for a polypus on the vocal cord (*Stimmlippe*). The operation was performed by Geheimrath Professor Dr. MORITZ SCHMIDT, and passed off quite smoothly. His Majesty has to refrain from using his voice until the wound resulting from the operation is healed.
>
> VON LEUTHOLD.
> MORITZ SCHMIDT.
> Potsdam, Nov. 7th, 1903 ILBERG.

The result of a microscopic examination carried out by Professor J ORTH is officially given in the following terms —

> The polypus consists of a very soft connective tissue containing only a few cells This tissue is covered by an epithelium of the pavement variety (*Plattenepithelium*), which is in regular layers and is everywhere sharply distinct from the connective tissue. Some of the cells in the connective tissue contain fine brown minute grains of pigment, which are evidently the result of previous small hæmorrhages. The polypus contains a considerable number of thin-walled blood vessels. It is therefore a case of an entirely benign polypus consisting of connective tissue.
>
> Berlin, Nov. 7th, 1903. Professor J. ORTH.

The feeling of every medical man on reading that in a man 45 years of age, whose father died from cancer of the larynx and whose mother succumbed to cancer of the breast, a laryngeal polypus had been discovered and removed was naturally one of uneasiness. We are certain that all our readers shared the public apprehension when first the news of the operation upon the German EMPEROR reached them. The report of the EMPEROR'S advisers, however, so far as it goes, is so very plainly expressed as to leave no doubt that in the piece removed, at any rate, there was nothing that justified a suspicion of malignancy. In that connexion the statement made by Professor ORTH—viz., that the epithelium everywhere was quite distinct from the connective tissue—is, of course, of the highest importance. Both Professor MORITZ SCHMIDT and Professor ORTH are authorities in their respective fields. The former is the learned surgeon who did not hesitate to pronounce the dreaded word cancer when he examined the then Crown Prince at San Remo exactly 16 years ago, and he would certainly not have undertaken an intra-laryngeal operation upon the EMPEROR, save merely for exploratory purposes, without previous consultation with other authorities if he had the least doubt in his mind as to the nature of the growth. Professor ORTH, moreover, would certainly have expressed himself much more guardedly and would not have spoken of the growth removed as "entirely benign" had the microscopic examination of the latter left any uncertainty as to its true nature. All these circumstances, as well as further reassuring statements as to the illustrious patient's condition, make it right for us to insist upon anticipation of a speedy recovery. The condition of the EMPEROR'S larynx will be carefully watched by his medical advisers and fuller clinical details will probably be given if it appears that any useful purpose would be served by so doing. The courage and good sense of the EMPEROR in taking the world into his confidence are to be commended. He has doubtless by so doing prevented the dissemination of much sinister rumour and much idle gossip.

Annotations.

"Ne quid nimis."

THE LATE LORD ROWTON.

THE rich and the poor, the masses and the ruling classes, will alike feel heartfelt regret at hearing of the death of Lord Rowton, which took place at his residence in London on Monday last, Nov. 9th. Lord Rowton was born in 1838, a grandson of the Earl of Belmore and nephew of the great Lord Shaftesbury. He received his education at Harrow and Cambridge, and after taking his degree was called to the Bar. It is said, and we believe with truth, that Lord Rowton, then Mr. Lowry Corry, first attracted Lord Beaconsfield's attention at a country house party by his cleverness in saving the situation from becoming dull. The story is told of different houses and with different details, but after some such introduction he became private secretary to the great statesman in 1866, a post which he continued to hold until in 1881 the association was dissolved by the death of his great friend. From that time the Lord Rowton of high social and diplomatic circles disappeared, to reappear as the founder of a remarkable and practical philanthropic movement. While engaged in the work of the Guinness Trust Lord Rowton conceived the idea of what he loved to call "poor men's hotels"—buildings which he intended to take the place of the wretched habitations known as common lodging-houses and to accommodate the deserving poor in a respectable manner at a reasonable expense. By many his plan at first was opposed as being almost impracticable, but he succeeded in getting Sir Richard Farrant, the then deputy chairman and managing director of the Artisans, Labourers, and General Dwellings Company, to build for him the first Rowton House. A site was secured in Vauxhall and the building was erected by Sir Richard Farrant at the net cost of the work, 5 per cent. only being added for the directors of the Artisans, Labourers, and General Dwellings Company. So important did we consider Lord Rowton's movement at the time as a practical contribution to the question of the housing of the poor that we made the first Rowton House the subject of a Special Commission, as we did also the second Rowton House which was built at King's Cross.[1] Since that time three other houses have been erected and a sixth is now in contemplation. Both in the provinces and abroad other companies have imitated the Rowton houses and the movement initiated by Lord Rowton is likely to spread widely inasmuch as he has shown the way to make philanthropy pay. The Rowton houses yield a 5 per cent. dividend, while catering in the kindest spirit for the poor. The great success of these institutions was due from the beginning to the personal interest taken in them by their originator. No detail was too insignificant for Lord Rowton to consider. He himself slept in the lodging-house beds to test their comfort and experimented with the angle which the backs of the seats should take in order that his lodgers might sit with ease. Nor did he omit to minister to the mental wants of his lodgers, as the pictures and panels on the walls of the houses and the books there provided amply testify. He knew the wants of his fellows; he had the sound sense to see that the rich and the poor, the well-born and the proletariat alike, need certain things to make their domestic environment a cheerful one as well as a sanitary one and he acted upon his views with the broadest sympathy. To the medical man it is a truism that "the colonel's lady and Mrs. O'Grady are just alike under their skin," but this knowledge is apt to be hidden from gentlemen born in the peerage and spending half a lifetime in exclusive political circles. Lord Rowton's intuition served him instead of education; he grasped the wants of the poor and setting out to relieve certain of them with courage and shrewdness he had the good fortune to see his efforts crowned with acknowledged success during his lifetime.

MALARIA IN INDIA AND THE COLONIES.

THE opening meeting of the session of the Royal Colonial Institute was held at the Whitehall Rooms, Hôtel Métropole, on Nov. 10th, the Right Hon. Sir George T. Goldie, K.C.M.G., being in the chair. After a brief address by the chairman on the necessity of the mother country waking up to the value of her Imperial possessions, Major Ronald Ross, professor of tropical medicine in the University of Liverpool, read a paper on Malaria in India and the Colonies. After showing the extent to which malaria prevails in the tropics to the detriment of the pioneer, the traveller, the planter, the engineer, and the soldier, the lecturer urged that the question how best to contend against the scourge is one of the greatest economical importance for an empire like the British He claimed that science had fully established three great laws concerning malaria: first, that it is caused by numbers of microscopical parasites which live and propagate themselves in the blood; secondly, that these parasites are carried from sick persons to healthy ones by the agency of a genus of mosquitoes called anopheles; and thirdly, that these kinds of mosquitoes breed principally in shallow and stagnant terrestrial waters. These laws, he pointed out, were now held by experts to satisfy nearly all the known facts about the disease. Passing to the question of prophylaxis, the value of mosquito nets, punkahs, and wire screens was dwelt upon, while quinine was stigmatised as no preventive, inasmuch as it does not exclude the parasite. But Major Ross pointed out that it was a great mistake to suppose that the whole subject of the prevention of malaria is contained within the formulæ of personal prophylaxis. "These will," he said, "enable individuals to protect themselves to a large extent, and if strenuous efforts are made to instil them into the general population it is to be supposed that a certain percentage of the public will take the trouble to adopt them. But every practical sanitarian knows by this time that if we depend solely upon personal prophylaxis for prevention of any disease we rely upon a broken reed. The fact is that the vast mass of the people will never believe in, or even seek to know, the principles of personal hygiene and will certainly not adopt them in spite of all our efforts. ...... For immediate results, at least in tropical and barbarous countries, we must look chiefly to State action." He then detailed the State measures for the repression of malaria which have already been tried in Sierra Leone, Havana, Lagos, Ismailia, the German colonies, Hong-Kong, and many other places, and with which our readers are familiar, and concluded by quoting and advocating a series of resolutions recently passed by the Chamber of Commerce in Liverpool, associated with members of the chambers of Manchester and London and of the Congress of the Royal Institute of Public Health. This joint meeting recommended, with special reference to West Africa, (1) that a fully qualified medical officer of health should be appointed to each of the principal West African towns; (2) that this officer should be supervised by a sanitary commissioner working on the Indian model of organisation; and (3) that an annual sanitary report regarding the West African colonies should be regularly published. Major Ross admitted that there were difficulties in the way of organising the definite and centralised sanitary scheme thus indicated. Of course, it might be found advisable after discussion to modify the details while retaining the principles. But he maintained that, if we wish for a continuous policy against malaria and the other grave diseases in the tropical colonies we must reorganise our sanitary system. A short discussion and a vote of thanks to Major Ross for his lecture brought the proceedings to a close.

[1] Report of THE LANCET Special Sanitary Commission on Private Action in Respect of Common Lodging-houses, THE LANCET, April 29th, 1893, p. 1017, and March 28th, 1896, p. 867.

A REMARKABLE CASE OF MULTIPLE PERSONALITY.

RECENT clinical investigations by physicians, especially of the school of Charcot, in regard to the subject of "double consciousness" have brought to light many facts of professional and medico legal interest. In the *Journal of Mental Science* for October Dr. Albert Wilson reports a remarkable case of multiple consciousness in the person of a young girl who at different times of her life exhibited the varying and different characters of one or other of a dozen "personalities." At the age of 12½ years the girl was attacked with influenza and cerebral meningitis lasting about six weeks. The multiplicity of personalities which she exhibited during her life began during this illness and in the following circumstances. In the third week of the illness she was delirious and maniacal and showed intense fear of imaginary snakes (visual hallucinations). She was mentally blind in that she could not recognise people, "yet a hand or any crease in the counterpane became to her a snake." Choreiform fits and opisthotonos occurred in the fourth week, the attacks being terminated by temporary coma. In the fifth week recovery set in and intelligence returned. In the sixth week there developed catalepsy and paraplegia and quite suddenly one day she developed into a different personality. Whilst in bed reading and playing with her dolls she "commenced to shake and clear a space around. Then she said, 'It is coming,' turned a somersault, and sat up in bed in this new personality." Her manner was now childish and her words were clipped as in baby talk, she also used words wrongly, calling white, black; black, white; and red, green. In this state she had some conception of her normal self whom she called "that person." She always says she is "very cross with that person for going and leaving her." She has frequent cataleptic attacks while in this state and is noisy and forward in manners, whereas in her normal state she is a modest and well-behaved child. Other personalities succeeded from time to time in the patient and as a rule she gave herself a different name in each case. Thus her next personality (No. 3) was called by her "Old Nick." This new personality made its appearance on July 24th, 1895, stayed till August 8th, and then disappeared for a year, returning on July 12th, 1896, when it continued for ten weeks. When in this personality the patient was able to read and to write and enjoyed good health but displayed a very bad temper. When she returned to a normal state she had no memory of events which had occurred to her in the "Old Nick" stage. In the character of a fourth personality she was both deaf and dumb. The deaf-mute condition recurred five times, its last appearance being in August, 1895. It lasted a few days only. Other personalities were of varying character and duration; one of these was named by her "good thing" or "good creature" or "pretty dear." This was the most intelligent of the numerous personalities and while in this stage she learnt French. Another personality was characterised by imbecility, blindness, and paraplegia. "The striking feature in this case was that when blind she could draw, while at no other period of her life, either normal or abnormal, had she any ability in drawing." Moral delinquency was exhibited in another of her personalities. She was then violent and cruel, bullied her little sister, and on one occasion she would have pushed the latter into the fire if help had not arrived. When she grew up to be about 16 years of age her normal personality had practically entirely vanished. She was sometimes the individual which she called a "thing" but more usually she was another—viz., "good creature." In some of her personalities, adds Dr. Wilson, habits of baby-talk and a forward unmaidenly manner existed and when menstruation was established no difference was produced in her mental condition. When 17 years of age she developed another personality in which she was self-willed, disobedient to her parents, subject to strong erotic impulses, and inclined to wantonness. In all, says Dr. Wilson, about a dozen different personalities, alternating or occurring at irregular intervals, constituted the total of her psychical life. "This opens the very serious question which constantly confronts us, that of responsibility" for acts done in such states of abnormal consciousness.

THE DANGERS OF SCHOOL ATTENDANCE.

MR. C. O. TREW, writing in the *Times* of Nov. 9th, points out that the great and proper desire of educational authorities to stimulate a high average attendance may lead to danger to the community. Where a cent. per cent. attendance is aimed at children are sure to be sent to school when they are physically unfit. To use Mr. Trew's words, though "absolutely incapable of receiving instruction through temporary or incipient malaise they are sent that they may not miss. Thus attendance is too often the seed of an epidemic." We feel that there is great force in this remark. The connexion of school attendance with epidemics of measles and diphtheria, for example, is so close that no efforts should be spared on the part of school authorities to weed out from among their flock children coming back to school before they have properly recovered, or attending school while in the early stages of disease or from an infected house. It is hard on the children and hard on the teachers that the prestige and the salary dependent on high average attendance should suffer because of the incidence of sickness, but all the world over illness is attended with inconvenience to others than the sick and so far as possible risks of infection through school attendance must be removed. The parents who despatch a sick child to school do not act in the interests of the child, or of his teacher, or of his fellow pupils and this fact requires recognition.

PRIMARY DIPHTHERITIC BRONCHITIS.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 16th M. Emile Sergent and M. Henri Lemaire described a case of the rare condition of primary diphtheritic bronchitis. A woman, aged 21 years, was admitted to hospital on Sept. 23rd suffering from intense dyspnœa. The history was that she had had bronchitis for eight days and that on the last two days the dyspnœa had been severe. The respirations were 40. Inspiration was stridulous and was accompanied by supra- and infra-sternal retraction. The voice was hoarse and almost inaudible. The face was slightly cyanosed. The throat was normal and the cervical glands were not affected. The pulse was 110 and the temperature was 101·5° F. On auscultating the chest the only abnormal sound heard was slight stridor; the vesicular murmur was almost absent. Dyspnœa of laryngeal or tracheal origin was suspected. As the thyroid was enlarged, the pupils were slightly unequal, and there was a well-marked collateral venous circulation in the sterno-clavicular region, this view was thought to be confirmed and dyspnœa from compression was suggested. Laryngoscopic examination revealed no lesion of the mucous membrane of the larynx but the vocal cords were in the paralytic position. Tracheotomy was performed and a mass of membrane escaped. The dyspnœa almost completely disappeared. The membrane yielded the diphtheria bacillus on culture. Antitoxin was given. On the following day membrane and bloody discharge issued from the tracheotomy tube and bronchitic râles were heard in the chest. Signs of broncho-pneumonia developed at the left base. On Sept. 26th a cast of the trachea and bronchi six inches long was discharged through the tube. The dyspnœa increased and death occurred on Sept. 29th. The necropsy explained the symptoms of compression. Below the right lobe of the enlarged thyroid was a large lymphatic gland four centimetres in diameter which covered the innominate veins. The mucous membrane of the trachea and main bronchi was red and covered with a greyish granular coating. The smaller bronchi were filled with a purulent fluid. At the bases of the lungs were patches of broncho-pneumonia. The bronchial and pulmonary lesions contained the diphtheria bacillus. Before tracheotomy the diagnosis of diphtheria was impossible.

PROFESSIONAL MEN AND MILITARY SERVICE.

MR. W. M. ANDERSON, house physician at Charing Cross Hospital, had recently to appear at Bow-street police-court charged with being an absentee from the training of the County of London Imperial Yeomanry (King's Colonials). For this offence he was fined £5 but as mention was made of a "case" to be stated there may remain a question of law to be argued with regard to his guilt. This cannot affect the facts given in evidence at the police-court as to the steps which led up to the charge against Mr. Anderson. The story told is hardly one likely to increase the popularity of the corps in question among would-be recruits of the class to which Mr. Anderson belongs, a class which may be competent and willing to perform its duty towards its country when able but which must at times be obliged to claim release from its obligations as a matter of necessity. Mr. Anderson had been for some time in the London Scottish, had served in the late war, and had joined the King's Colonials on his return from South Africa, being then a medical student, and not house physician at a general hospital. Finding after his appointment that his duties were incompatible with his attendance at the requisite number of drills and at the annual training in camp he applied five or six weeks before the last training took place for his discharge. In order to obtain this certain requirements had to be fulfilled with regard to the return of clothing and equipment and the settlement of a small sum of money due to the regiment, the precise amount of which in Mr. Anderson's case appears to have been, and still to be, in dispute. The mere civilian would think that a reply stating these conditions would have been promptly sent and that on their being complied with the discharge would have been granted. This, however, was not done, as Mr. Anderson was apparently deemed to be informed of the terms upon which discharge could be obtained owing to these being displayed at the orderly room. Mr. Anderson further wrote on the subject to his commanding officer, but a trooper may not write to a colonel, not even if he is a busy professional man, ignorant or oblivious of the disciplinary regulations of the army, so the next occasion on which Mr. Anderson heard of the matter was when a police constable took him into custody at the hospital and escorted him through the streets to answer for his delinquencies. He mentioned also in his evidence an occasion previously to his arrest when a visit to the orderly room did not produce the information and facilities which he required. This, however, and other matters will no doubt be considered by those responsible for the regiment to which he belonged, or belongs, and it is to be hoped that they will realise that while the citizen soldier is willing to put himself to considerable inconvenience and to some expense in order to make himself as efficient a fighting man as he reasonably can, he must be allowed a certain amount of latitude and consideration when not actually standing in the ranks. The employment of a little tact and the relaxation of red tape whenever possible are alike essential so long as the present system of voluntary service in the auxiliary forces is retained. If this were not generally recognised cases like that of Mr. Anderson would frequently arise in other corps than that from which he sought to be discharged.

THE STATUS THYMICUS AND SUDDEN DEATH.

THERE is probably no form of sudden death which has received so much attention from the medical profession in recent years as that form associated with hyperplasia of the thymus gland and of the lymphatic apparatus in general known as the status thymicus. An account of this abnormal constitutional condition was given in an annotation in THE LANCET some time ago.[1] In the *Johns Hopkins Hospital Bulletin* for October Dr. G. Blumer, professor of pathology at Albany Medical College, gives a detailed account of his studies of this interesting affection. Attention is called to the fact that a similarity between the lesions observed post mortem in cases of status thymicus and many cases of death under anæsthetics has been traced by several observers. These facts are important from a professional and a medico-legal point of view, for it is necessary that we should recognise "the existence of a class of individuals, the subjects of a peculiar constitution which renders them extremely susceptible to shocks of various kinds, physical, psychical, and toxic, and which may lead to sudden death from accidents which to the ordinary individual would be trivial." Instances are on record, adds Dr. Blumer, where individuals of thymic constitution have died from the shock of a plunge into cold water and the case of the child mentioned by Professor Langerhans, who died a few minutes after the administration of diphtheria antitoxin, is familiar to medical men. A number of cases are also on record where nursemaids and women in charge of infants have been accused of suffocating them when the true cause of death has been shown by post-mortem examination to be asphyxia or syncope occurring in the status thymicus. This morbid condition frequently co-exists with other constitutional affections or diatheses, such as rickets, epilepsy, and ophthalmic goitre, but these are to be regarded as coincidences or accidental associations. Dr. Blumer's own investigations included nine cases of status thymicus with sudden death occurring in infants and children and a study of all the cases recorded in medical literature. The reported pathological anatomy and histology are essentially the same, adds Dr. Blumer, in all the cases recorded but the bacteriology of the affection is unknown. The recognition that the enlarged thymus gland is essentially part of a general hyperplasia of the lymphatic system is due especially to Paltauf of Vienna. In some cases, and particularly in adults, the lymphatic hyperplasia is associated with a hypoplasia of the heart and aorta similar to that described by Virchow in chlorotic subjects. Escherich, who has specially studied the features of the thymic constitution, refers to the following valuable diagnostic features of the affection, with which Dr. Blumer concurs. The patients have a pale thin skin, a pasty complexion, and a good pad of subcutaneous fat. Frequently signs of rickets or of scrofula are present and the superficial lymphatic glands of the neck and the axilla are enlarged. There is hypertrophy of the tonsils and circumvallate papillæ, and naso-pharyngeal adenoids are often present. The spleen is frequently palpable. "Many of these patients seem to enjoy perfect health up to the time of their unsuspected death." Referring to the large number of cases personally observed or recorded in literature of infants suspected of being the victims of "overlying" Dr. Blumer states his belief that some of these must be regarded as the victims of the status thymicus. "In one case the child had no appetite on the evening of its death, in another slight convulsions ('moving and struggling' of the child) were noticed by the mother who was looking through a window a few yards off. On her coming to the child a few minutes later it was found to be dead." A second class of cases is mentioned by Dr. Blumer and Dr. Nordmann where a child has died almost instantly from collapse when immersed in cold water. A third class of cases includes deaths from so-called thymic asthma, an attack of asphyxia of obscure nature not to be confounded with laryngismus stridulus. Lange states that in thymic asthma there is throughout the attack a regular "sighing" respiration which does not occur in laryngismus stridulus. Some cases of death in the status thymicus show accelerated respiration, cyanosis, dilatation of the pupils, and swelling of the veins in the neck, and death follows in a few minutes (Gerhardt, Somma, and Blumer). Laub has described a cerebral form of death from the status thymicus occurring in young adults. The onset is marked by epileptiform convulsions and coma. Albuminuria is present and vomiting occurs. Post-mortem examination shows the presence of the status thymicus and cerebral œdema. Subjects of the status thymicus have been noted to be specially prone to death under surgical anæsthesia (Bayer, von Kundrat, Hinkel, and Blake). Blake, who has specially studied cases in the United States of America, has found that ether is as dangerous as chloroform in such cases. "It would seem," adds Dr. Blumer, "as though two classes of patients were especially liable to this [fatal] accident, patients with simple or exophthalmic goitre and patients with adenoid vegetations." The gross lesions found post mortem in cases of the status thymicus include hyperplasia of the thymus, the spleen, and the lymphatic glands generally, a hypoplasia of the heart and the great vessels, especially marked in pubescent and adolescent subjects, and focal lesions in the spleen and the tonsils (hypertrophy of lymph nodules and foci of degeneration in the same). Cultures from the lymphatic glands and the fluids of the body in several cases (Lartigan and Blumer) gave negative bacteriological results. As to the cause of death Dr. Blumer agrees with Escherich that a toxæmia due to the abnormal disorder of the *lymphatic system occurs intermittently in the subjects of* the status thymicus. "We would suggest," concludes Dr. Blumer, "that individuals born with the thymic constitution have an instability of the lymphatic mechanism, so that intermittent lympho-toxæmia is produced. During such attacks the patients are especially susceptible to the action of bacteria and chemical poisons and to all physical and psychical shocks which at these times may cause death under circumstances which would be trivial to the normal individual."

[1] THE LANCET, March 24th, 1900, p. 869.

THE NATIONAL ANTI-VACCINATION LEAGUE.

THE annual conference of the National Anti-Vaccination League was held at Glasgow on Nov. 7th. Lieutenant-General Phelps was in the chair and the meeting proceeded to consider the eminently sensible recommendations of the Imperial Vaccination League. The letter by Mrs. E. Garrett Anderson, M.D., entitled "Vaccination and the Rates," which appeared in the *Times* of Sept. 15th, 1903, and in which that lady suggested that all employers should insist upon their employés being able to prove that they had recently been efficiently revaccinated, seems to have greatly exercised the anti-vaccination mind. Dr. W. R. Hadwen of Gloucester stigmatised Mrs. Garrett Anderson's methods as "subtle, disgusting, and contemptible." The President read a paper in which he contended that vaccination, especially that performed with calf lymph, was capable of producing cancer. We should much like to see Dr. Hadwen, Lieutenant-General Phelps, and other prominent anti-vaccinationists offer themselves as nurses or attendants in a small-pox hospital. Unfortunately, however, the brutal and overbearing authorities have so little regard for the liberty of the subject that they will not allow anyone to serve in a small-pox hospital until he or she has been vaccinated, so that this test is impossible of attainment. The conference passed various motions, one of which stigmatised pressure used by employers on the advice of Mrs. Garrett Anderson and the Imperial Vaccination League to force employés to submit to revaccination as a condition of employment as unwarranted, tyrannous, and calculated to undermine the independence of the working classes. We can only hope that the Imperial Vaccination League will continue its good work and will be amply provided with funds for the purpose. Subscriptions (10*s.* 6*d.* for members and not less than 2*s.* 6*d.* for associates annually) may be sent to the secretary, Imperial Vaccination League, 53, Berners-street, London, W.

TUBERCULIN IN THE TREATMENT OF LUPUS.

THE employment of Koch's tuberculin in the treatment of lupus is at the present time somewhat rare and therefore a paper published in the present issue of THE LANCET is of great interest. In that article Mr. C. Stanser Bowker of Newport describes seven cases of lupus which he treated by excision and the subcutaneous injection of Koch's lymph. Fowler's solution of arsenic was also injected. In some of the cases the injections were continued for several months, until, in fact, no reaction followed. The results show the success which can be obtained by this method. It will be seen that the chief point in the treatment adopted is the combination of the tuberculin injection with the excision. The cosmetic results appear to have been very good and altogether the treatment seems to have been satisfactory. It is well, of course, to remember at the present day that other methods than light and x-ray treatment can produce successful results in lupus, but we must confess that we think that the employment of the x rays would have materially shortened the duration of treatment in some at least of these cases.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE next quarterly or general meeting of the above society will take place at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. Ernest W. White, immediately after the extraordinary general meeting which is summoned for 3 o'clock in the afternoon of Wednesday, Nov. 18th. Dr. Nathan Raw will read a paper on the Relation of Mental Symptoms to Bodily Disease with special reference to the Treatment of Temporary Forms of Insanity *outside* Lunatic Asylums. Dr. R. S. Stewart will read a paper entitled "The Mental and Moral Effects of the South African War, 1899–1902, on the British People." These papers will be preceded by a short lantern demonstration of microscopical slides illustrating Fragilitas Ossium in the Insane by Dr. W. Maule Smith. The members will afterwards dine at the Café Monico, Piccadilly Circus, W., at 7 o'clock, the price of the dinner ticket being 7*s.* 6*d.* Names of those intending to dine should be sent to Dr. T. Outterson Wood, 40, Margaret-street, Cavendish-square, London, W.

RADIUM IN CANCER.

A QUANTITY of pure radium has been generously placed at the disposal of a member of the staff of the Cancer Hospital, Fulham-road, London, S.W., and the staff are making arrangements for an extensive trial of this new method of treatment. With the number of inoperable cases at their disposal the staff will be able to give the treatment a fair and exhaustive trial.

RESIGNATION OF THE VIENNA MEDICAL CHAMBER.

THE members of this chamber, to which is confided the professional control of the medical men in Vienna, resigned in a body on Nov. 7th. This is one result of a struggle which has been continued for some time between the anti-Semites who are members of the Landtag with the Governor of Lower Austria on the one side and the Viennese medical men and university professors, who are mostly Jews, on the other. The quarrel is stated to have begun in connexion with the question of vivisection, a number of members of the Diet having accused the medical men of making experiments on animals in contravention of the vivisection law, of performing illegal operations on poor people, and of surreptitiously obtaining parts of dead bodies. Our Vienna correspondent's report shows that the whole movement is anti-Semitic rather than sentimental.

A POPULAR EXPOSITION OF ANKYLOSTOMIASIS.

THE principal journals connected with the technical trades and industries follow the sound policy of very seldom admitting medical questions into their columns, but it is an old maxim that circumstances justify occasional departures from general rules and the *Colliery Guardian*, recognising this, has appointed a special commissioner to write for it a series of articles on ankylostomiasis. Our readers are familiar with the fact that this intestinal parasite, so common in the tropics, many years ago attracted attention on account of the havoc which it caused among the men engaged in railway tunnelling in Switzerland, and we have also had to record that the parasite has now made its appearance amongst miners both in Germany and more recently in Cornwall.[1] The first article, described as "introductory," appeared in the *Colliery Guardian* of Nov. 6th and is evidently the work of a very competent writer. It deals with the natural history and appearance of the parasite, the treatment of the disease, and the prophylactic measures required. This latter is, of course, by far the most important part of the subject and resolves itself into inducing the men not to defecate on the ground in the mines. Our contemporary gives copious illustrations, not only of the parasite and its eggs in various stages of development, but also of the arrangements of water-closets, dry-earth closets, and baths provided above ground by Westphalian and Belgian mine owners for the use of the men. Of more consequence still, however, is the system of pails provided for defecation underground. It is hardly to be expected that the average pitman will welcome these innovations rapturously, and one effect which may be expected from the treating of this subject in a non-medical journal will be that persons occupying positions of some authority in mines will gradually become convinced of the advantage of carefully attending to the measures of prevention which helminthologists and medical men have long ago defined. It will be useless to leave the matter in the hands of the men; supervision will be required. In forthcoming articles the history of the outbreak at Brennberg in Austria will be described and a detailed account given of the regulations issued by the German Government for the purpose of combating the disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THREE lectures on the Development and Morphology of the Sternum have just been delivered in the Royal College of Surgeons of England by Professor Andrew Melville Paterson (Hunterian Professor). The concluding lecture, which was delivered yesterday (Friday), dealt with (1) variations in the form of the sternum; (2) its comparative anatomy and morphology; and (3) its teratology. Three lectures on the Early Stages in the Development of Mammalian Ova and the Formation of the Placenta in different Groups of Mammals will be delivered in the theatre of the College by Professor Arthur Robinson (Hunterian Professor) on Nov. 16th, 18th, and 20th, at 5 P.M. each day. The first lecture will deal with the structure of the ovum, its coverings, maturation, fertilisation, and segmentation. The second and third lectures will describe the formation and the structure of the placenta in a variety of animals and in the human subject.

SPONGES IN MILITARY SURGERY.

THE *Deutsche Militärärztliche Zeitschrift* for July, 1903, contains an article, written in collaboration by Dr. Deeleman and Dr. Varges, on the employment of sponges for surgical purposes on active service. Of late years bacteriology has demonstrated the fact that in spite of attempts at disinfection and sterilisation sponges that have been used for hospital work are liable to convey contagion. The practice amongst surgeons at present is to dispense as far as possible with the use of sponges and after an initial exposure to contamination to discard them altogether. In the opinion of Dr. Deeleman and Dr. Varges there is in reality no need for this extravagance, especially on active service where bulk and weight are most important considerations with regard to surgical material. Disinfection by steam under pressure or by boiling in plain water, or in soda solutions, or in antiseptic solutions of any description is inadvisable, because the sponges are made hard during the process and lose, moreover, their elasticity. According to the regulations in force in the German army the process of sterilisation for sponges should be carried out in the following manner. In the first place as much of the foreign matter as possible should be got rid of by repeated washings in hot water. The sponges are then to be immersed during 12 hours in an aqueous solution of corrosive sublimate (5 per 1000), to which glycerine in the proportion of 20 per cent. has been added. Dr. Deeleman and Dr. Varges believe that this procedure occupies more time than could usually be spared on active service. No doubt corrosive sublimate is the best of all disinfectants, but on a campaign it is necessary that its antiseptic action should be facilitated by the preliminary removal of coarse impurities such as blood and pus in some quicker way than by washing in hot water. In their opinion sponges that have been used should first be placed for 15 or 30 minutes in hot water containing 5 per cent. of ammonia (density 0·960). Having been removed and squeezed they should next be washed in a 5 per cent. carbolic solution until they part with their viscosity and become once more soft and elastic. The sterilisation is then to be completed by immersion during two hours in the ½ per cent. solution of corrosive sublimate. Should time press the duration of the steeping may be shortened to one hour provided that the temperature of the sublimate solution be at least 50° C. Dr. Deeleman and Dr. Varges have verified this process by bacteriological experiment. Thanks to it complete sterilisation of moderate-sized sponges can be effected in three, or at most four, hours, whereas according to the official method the time occupied is 12 hours. Sponges for use on active service should not be packed in canvas but should be compressed and placed in bags made of sterilised parchment.

[1] THE LANCET, Nov. 22nd (p. 1391), 1902; March 14th (p. 765), ay 2nd (p. 1276), and June 27th (p. 1833), 1903.

THE SOCIETY OF ARTS.

THE Society for the Encouragement of Arts, Manufactures, and Commerce, to give that well-known body its full title, is now entering on its 150th session and the opening meeting will be held on Nov. 18th at the society's rooms, John-street, Adelphi, W.C., when an address will be delivered by Sir William Abney, vice-president and chairman of the council. The Wednesday evening meetings will commence on Nov. 25th, when Mr. G. F. Parker will give an address on the Universal Exposition to be held at St. Louis, U.S.A., in 1904. The Cantor Lectures, delivered weekly on a variety of technical subjects of interest, will commence on Nov. 23rd and will continue up to the month of May.

THE TESTING OF THE EYES OF SCHOOL BOARD CHILDREN.

SOME correspondence has recently taken place between the secretary of the London Hospital and the authorities of the School Board for London dealing with a question of considerable importance—namely, upon whom devolves the duty of testing the eyesight of the School Board children? The circumstances of the case are these. On Oct. 6th last a letter was addressed by the secretary of the London Hospital to the School Board for London complaining that so large a number of children had been sent from the Board to have their eyesight tested as seriously to interfere with the ordinary work of the surgeon in charge of the ophthalmic department and that this gentleman, Mr. A. B Roxburgh, found himself unable to examine them in a manner satisfactory to himself or advantageous to the children; that, as a matter of fact, there were no less than 180 cases waiting to be tested and that 50 had presented themselves on a single day. The secretary added that Mr. Roxburgh had stated that he did not feel himself able to attend on any one day to more than ten School Board cases in addition to his ordinary work, and the committee of the hospital had given instructions that for the present, pending the action of the School Board, no more eye-testing should be done for the Board at the hospital. The reply of the School Board, founded on its own medical officer's report, was to the effect that no instructions were given to the parents the eyesight of whose children was defective to apply to any particular hospital, but that they *were simply recommended to procure medical advice and* that in the opinion of the Board it was the duty of the officer in charge of the ophthalmic department of the hospital to attend to all cases that presented themselves. It was broadly hinted that if the ophthalmic surgeon and his assistants were unable to cope with the increase of the patients it would be well for the hospital to augment the staff. The School Board took the opportunity of bringing under the notice of the committee of the London Hospital two cases, both of which, it would appear, were particularly hard. In one the child, though wet, poorly clad, badly shod, and hungry, was stated to have been refused attention simply on the ground that she had come from the London School Board; in the other it was alleged that the patient, after waiting for two hours, was dismissed without being attended to because the surgeons were sick and tired of the London School Board cases. We do not take for granted the accuracy of this account of the demeanour of the hospital officials, but any how they could plead that they were only acting in accordance with their instructions. We desire to consider the real gist of the matter. The time at the disposal of a surgeon in active practice to spend on gratuitous patients is not unlimited. Most of the cases sent by the School Board to procure medical advice were probably cases of asthenopia arising from hyperopia, and in some more or less astigmatism would *certainly be present. If from ten minutes to* a quarter of an hour be allowed for the determination of an uncomplicated case of hyperopia, and half an hour for a case of hyperopia complicated with astigmatism, a much longer time and two or three visits being sometimes required, it is clear that the demand on the time of even half a dozen assistants is immense and that allowance must be made for the best-tempered man when in addition to all his other work, including operations, he is suddenly confronted with 50 new cases in which the refraction has to be ascertained with an approach to accuracy. It hardly seems fair that the duty of attending and prescribing appropriate glasses for so many cases should rest with the hard-worked surgeon of a special department of a general hospital, whose time is necessarily to a large extent otherwise occupied.

IN the list of Birthday Honours are included the names of Mr. J. G. Craggs, honorary secretary of King Edward's Hospital Fund, and Mr. A. R. Manby, M.V.O., M.D. Durh., surgeon-apothecary to the King and the Prince of Wales. Both these gentlemen well deserve the knighthood which has been conferred upon them. Captain T. H. M. Clarke, D.S.O., R.A.M.C., has received a Companionship of the Order of St Michael and St. George for services in Crete, and Mr. Robert Bell, M.D., F.R.S., acting director of the Department of Geological Survey, Canada, has been appointed a Companion of the Imperial Service Order.

THE annual dinner of the British Gynæcological Society will take place at the Café Monico, Piccadilly Circus, London, W., on Friday, Nov. 27th, at 7.30 P.M. Communications on the subject should be addressed to the honorary secretaries, Dr. J. H. Swanton, 40, Harley-street, Cavendish-square, W., and Dr. S. J. Aarons, 14, Stratford-place, W.

THE fifth annual dinner of the Medical Graduates' College and Polyclinic will be held at the Trocadéro Restaurant, Piccadilly Circus, London, W., on Thursday, Dec. 3rd, at 7 30 P.M. Mr. James Cantlie will preside. Those wishing to be present should communicate with Mr. A. E. Hayward Pinch, 22, Chenies street, W.C.

THE next session of the General Council of Medical Education and Registration of the United Kingdom will commence on Tuesday, Nov. 24th, at 2 P.M. at 299, Oxford-street, London, W, the President, Sir William Turner, K.C.B., in the chair.

ON Nov. 6th Mr. John Newport Langley, D.Sc., F.R.S., Fellow of Trinity College, was elected to fill the professorial chair in physiology in the University of Cambridge, vacant by the resignation of Sir Michael Foster, M.P.

Dr. Charles J. Martin, F.R.S., has now entered upon his duties as director of the Lister Institute of Preventive Medicine and in future the administrative work of the institute will be under his control.

Her Majesty the Queen has graciously consented to become the first Lady Governor of St. Bartholomew's Hospital.

ST. BARTHOLOMEW'S HOSPITAL.

AT a general court of governors held on Nov. 5th, about 70 governors being present, the following motions, which were proposed by Mr. CHARLES ALFRED CRIPPS, K.C., M.P., and seconded by Sir WILLIAM S CHURCH, Bart., K.C.B., President of the Royal College of Physicians of London, were carried with only one dissentient, viz. :—

1. That this court desires to record its unqualified satisfaction that the Mansion House Committee, after impartial and exhaustive inquiry, have come to the following conclusions, viz : (*a*) That it is impossible, in the public interest, to remove the hospital from its present site; (*b*) that the additions to, and re arrangement and improvement of, the existing buildings, as proposed by the governors, are absolutely necessary for continued efficiency in the treatment of patients and for bringing the hospital in all departments up to the standard of modern sanitary and scientific requirements; (*c*) that an appeal to the public to supply the cost of the requisite new buildings and improvements is fully justified, it having been shown to be impossible for the hospital to provide the same out of its own resources; (*d*) that the reputation and character of the hospital have been fully vindicated and that its administration has been conducted in a wise and enlightened spirit with due regard to economy and to the best interests of the patients.

2. That the court begs to offer to the gentlemen who served on the Mansion House Committee its cordial thanks for the large amount of time and the great attention bestowed by them on all matters connected with their inquiry.

3. That in the general scheme of rebuilding provision be made for: (*a*) additional operating theatres; (*b*) new casualty and out-patient departments; (*c*) new nurses' home; (*d*) new quarters for the resident medical and surgical staff; (*e*) an isolation block and other new ward blocks to supply the place of those to be demolished; (*f*) new mortuary, post-mortem rooms, and pathological department; (*g*) internal structural re-arrangement of the east, west, and south wings of the hospital.

4. That the house committee with power to add to their number be requested to determine, after consultation with the medical staff, by which of the several plans submitted by the architects, subject to such modifications a from time to time appear desirable, provision for the foregoing purposes can best be secured; but that it be an instruction to the house committee to carry out the recommendation of the Mansion House Committee as regards the out-patient department as shown on Plan No. 6 laid before that committee.

5. That the first block to be built be the new casualty and out-patient departments, dispensary, &c., and the new operating theatres; that the nurses' home be next built; and that the remaining blocks be built in such order as, having regard to their relative urgency, may be considered most expedient and convenient for the general work of the hospital.

6. That the medical staff be consulted from time to time on all details that affect the sanitary arrangements, the treatment of the patients, or the interests of the medical school.

7. That the treasurer and almoners be authorised to make arrangements from time to time for the temporary use of such of the Christ's Hospital buildings as may be necessary for carrying on the work of the hospital. Also that they be given authority to make any provision they may think proper for officers and servants whose present quarters are destroyed or interfered with thereby.

8. That application be made to Parliament in the ensuing session for power to the governors to use for the purposes of the hospital in connexion with the proposed new buildings and improvements the site of the church of St. Bartholomew-the-Less and the burial ground adjoining within the hospital precincts, and for the union for ecclesiastical purposes of the parish of St. Bartholomew-the-Less with the adjacent parish of St. Bartholomew-the-Great.

9. That after the Lord Mayor elect has entered upon office the treasurer and almoners do wait upon him with a request from this general court of governors that at some convenient date he will convene a meeting of the citizens for the purpose of raising the requisite funds for the new buildings and improvements needed.

ASYLUM REPORTS.

Cork District Asylum (Annual Report for 1902).—The average number of patients resident during the year was 1613, comprising 867 males and 746 females. The admissions during the year amounted to 308—viz , 160 males and 148 females. Of these 267 were first admissions. Dr. Oscar T. Woods, the medical superintendent, states in his report that the admissions during the year are 15 over the average of the last ten years. "Many of these were caused by attacks of insanity coming on at the age of puberty, in almost all of whom there was an hereditary predisposition." The recovery-rate is greater among the married than among the single, so that "there are at present in the asylum 1053 single and only 393 married patients." "In many of my annual reports," says Dr. Woods, "I have recorded my opinion that until a definite effort is made to check its hereditary transmission insanity will go on increasing; intoxications, ill-health, &c., act as exciting causes to bring on insanity; but in nearly all these cases there is the predisposing cause of heredity lying dormant to be lit up at the critical epochs of life by any exciting cause." Reviewing the type of patients admitted into the asylum, says Dr. Woods, "I have formed a strong opinion that there is much unregistered insanity still in the country and much neurotic disease existing to be turned into active insanity by the slightest exciting cause." The number of patients discharged as recovered during the year amounted to 122—viz., 53 males and 69 females, or 7·6 per cent. of the average number resident. The deaths during the year amounted to 106, or 6·6 per cent. as calculated on the same basis. Of the deaths one was due to general paralysis of the insane, four were due to cerebral hæmorrhage, five to senile decay, nine each to bronchitis and cardiac disease, 16 to cerebral atrophy, 34 to pulmonary and other forms of tuberculosis, and the rest to other causes. The inspector of lunatics states in his report that while the condition of the asylum "is in many respects satisfactory and the time and care which the medical superintendent devotes to his duties are beyond all praise, it cannot be pretended that an institution for the insane fulfils its primary object when it does not afford sufficient accommodation for the number of patients needing its shelter." It is pointed out that the overcrowding which exists at present should be relieved. The nursing and care of the patients are stated to be excellent. It is also pointed out that the provision of increased accommodation is a question which can no longer be postponed but should be practically met and settled by the committee of management which seems to have been hitherto rather lax in discharging this obligation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8743 births and 4691 deaths were registered during the week ending Nov. 7th. The annual rate of mortality in these towns, which had been 15·8, 15·9, and 16·3 per 1000 in the three preceding weeks, declined again last week to 16·2 per 1000. In London the death-rate was 16·1 per 1000, while it averaged 16·3 in the 75 other large towns. The lowest death-rates in these towns were 5·7 in King's Norton, 6·4 in Walthamstow, 7·4 in Newport (Mon.), 8·0 in Hornsey and in Smethwick, 8·3 in Bournemouth, 8·7 in Hastings, and 8·8 in Leyton and in Portsmouth; the highest rates were 20·8 in Gateshead and in Tynemouth, 21·0 in Oldham, 22·0 in Burnley, 22·3 in Salford, 22·4 in Swansea, 22·6 in Wigan, 22·8 in Warrington, and 23·4 in Stockport. The 4691 deaths in these towns last week included 419 which were referred to the principal infectious diseases, against 635, 532, and 523 in the three preceding weeks; of these 419 deaths, 158 resulted from diarrhœa, 56 from "fever" (principally enteric), 55 from measles, 55 from diphtheria, 54 from whooping-cough, and 41 from scarlet fever, but not one from small-pox. No death from any of these principal infectious diseases was registered last week in Croydon, Willesden, Hornsey, Hastings, Brighton, Devonport, Smethwick, Derby, or Wallasey, while they caused the highest death-rates in Ipswich, Hanley, Warrington, Rotherham, York, Sunderland, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Ipswich, Warrington, Rotherham, and Sunderland; from scarlet fever in Northampton and Merthyr Tydfil; from diphtheria in Hanley; from whooping-cough in Rochdale and Halifax; and from diarrhœa in Hanley, King's Norton, Gateshead, and Newcastle-on-Tyne. The mortality from "fever" showed no marked excess in any of the large towns. No death from small-pox was registered last week in any of the 76 large towns. The Metropolitan Asylums hospitals contained 43 small-pox patients at the end of last week, against 11, 34, and 42 at the end of the three preceding weeks; five new cases were admitted during the week, against one, 26, and 12 in the three preceding weeks. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital, which had been 1861, 1858, and 1828 on the three preceding Saturdays, had risen again to 1854 on Saturday last, Nov. 7th; 224 new cases were admitted during the week, against 208, 209, and 199 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 175, 194, and 260 in the three preceding weeks, further rose last week to 271, but were 27 below the number in the corresponding period of last year. The causes of 54, or 1·2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Leeds, Newcastle-on-Tyne, and in 45 other smaller towns; the largest proportions of uncertified deaths were registered in Northampton, Liverpool, St. Helen's, Preston, Gateshead, and Rhondda.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·1, 16·7, and 17·0 per 1000 in the three preceding weeks, declined again to 15·8 per 1000 during the week ending Nov. 7th, and was 0·4 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·8 in Dundee and in Greenock and 13·8 in Paisley, to 16·9 in Glasgow and 23·2 in Perth. The 516 deaths in these towns last week included 19 which were referred to measles, 15 to diarrhœa, six to diphtheria, six to whooping-cough, five to scarlet fever, one to small-pox, and one to "fever." In all, 53 deaths resulted from these principal infectious diseases last week, against 72, 77, and 62 in the three preceding weeks. These 53 deaths were equal to an annual rate of 1·6 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 14, 16, and 11 in the three preceding weeks, rose again last week to 19, of which 18 occurred in Glasgow. The deaths from diarrhœa, which had been 35, 39, and 33 in the three preceding weeks, further declined to 15 last week, and included six in Glasgow, four in Dundee, and three in Aberdeen. The fatal cases of diphtheria, which had been four and five in the two preceding weeks, further rose last week to six, of which four were registered in Glasgow and two in Edinburgh. The deaths from whooping-cough, which had been eight and seven in the two preceding weeks, further declined to six last week and included two in Glasgow and two in Edinburgh. The fatal cases of scarlet fever, which had been four in each of the two preceding weeks, increased last week to five, of which two occurred in Glasgow and two in Edinburgh. The death from small-pox was registered in Glasgow where the fatal case of "fever" also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 82, 92, and 108 in the three preceding weeks, declined to 107 last week and were 43 below the number in the corresponding period of last year. The causes of 18, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·6, 21·5, and 21·2 per 1000 in the three preceding weeks, rose again to 21·7 per 1000 during the week ending Nov. 7th. During the past four weeks the death-rate has averaged 20·8 per 1000, the rates during the same period being 15·6 in London and 14·7 in Edinburgh. The 158 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week and included two which were referred to the principal infectious diseases, against nine, 13, and seven in the three preceding weeks; of these two deaths, one resulted from "fever" and one from diarrhœa. The death-rate from these diseases was 0·3 per 1000; the death-rate from the principal infectious diseases last week was 1·4 per 1000 in London and 1·1 in Edinburgh. The 158 deaths in Dublin last week included 32 of children under one year of age and 39 of persons aged 60 years and upwards; the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons were somewhat in excess. Three inquest cases and two deaths from violence were registered, and 61, or more than a third, of the deaths occurred in public institutions. The causes of nine, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been appointed Surgeons:—Arthur Robertson Brailey and Frank Wybourn Smith.

The following appointments are notified:—Surgeons: E. Cooper to the *President* for three months' hospital study and P. H. Bannister to the *Northampton* (dated Nov. 11th); and W. R. Center to the *Pembroke* (dated Nov. 7th).

ARMY MEDICAL STAFF.

Colonel W. L. Gubbins, M.V.O., Royal Army Medical Corps, to be Surgeon-General, vice Sir W. D. Wilson, K.C.M.G., retained on the Active List as a Supernumerary to the Establishment (dated August 27th, 1903).

ROYAL ARMY MEDICAL CORPS.

Colonel G. D. N. Leake, Principal Medical Officer at Woolwich, will shortly embark for duty in India. Captain A. E. C. Keble is appointed to the medical charge of the Hospital for Soldiers' Wives and Children, officers of the staff, and their families, Chatham, vice Lieutenant-Colonel R. Jennings.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Majors to be Surgeon-Lieutenant Colonels (dated Nov. 11th, 1903):—R. R. Brown, A. D. MacDonald, C. Arrol, W. J. Naismith, D.S.O., E. W. Symes, R. De La P. Beresford, C. W. Thorp, T. J. Aubin, R. B. Smith, R. T. Cæsar, E. B. Reckitt, R. A. S. Daly, A. Chawner, E. J. Lawless, F. E. Fenton, F. L. Stevenson, R. L. Sparrow, F. J. Walker, W. C. Cowan, A. T. Wear, J. H. Maclean, W. Fergusson, W. L. Stewart, J. W. Hodgson, and A. Lingard.

The undermentioned Surgeon-Captains to be Surgeon-Majors (dated Nov. 11th, 1903):—C. N. Lee, R. T. Meadows, J. G. Saville, G. M. Lowe, F. V. Adams, D. T. Key, E. H. Moore, R. J. M. Coffin, S. S. Hoyland, J. Adam, W. Kinnear, H. R. Bramwell, J. A. Rigby, J. T. Thomas, W. L. Edwards, and H. J. Mackay.

The undermentioned Surgeon-Lieutenants to be Surgeon-Captains (dated Nov. 11th, 1903):—C. Boyd, J. Taylor, E. M. Callender, H. G. O. Collett, E. W. Livesey, J. P. S. Ward, J. S. Mackay, L. W. Pockett, R. T. Ferguson, C. G. Maclagan, J. M. Moir, W. A. Griffiths, R. H. Luce, A. H. Vernon, J. C. Wright, G. Melville, J. McMullen, D. R. Doble, E. W. F. MacW. Bourke, A. Henderson, E. E. Dyer, A. Y. Pringle, J. S. Swain, H. M. Brownfield, H. N. A. Taylor, T. F. Devane, A. Ehrmann, H. Fox, L. L. Hanham, and A. Hilton.

Surgeon-Lieutenant-Colonel C. M. MacKnibban having attained the prescribed limit of age is removed from the Army Medical Reserve of Officers.

Surgeon Captain C. A. Corke, 2nd Volunteer Battalion Worcestershire Regiment, to be Surgeon-Captain (dated Nov. 7th, 1903).

Lieutenant A. E. L. Wear, Royal Army Medical Corps Volunteers, to be Surgeon-Lieutenant (dated Nov. 7th, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Middlesex: Surgeon-Lieutenant E. A. Snape to be Surgeon-Captain (dated Nov. 7th, 1903).

Royal Engineers (Volunteers): 1st West Riding of Yorkshire (Sheffield): Alan Charles Turner to be Surgeon-Lieutenant (dated Nov. 7th, 1903).

Rifle: 3rd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Captain J. McMullen is retired under paragraph 118 Volunteer Regulations (dated Nov. 7th, 1903). 2nd (Westmoreland) Volunteer Battalion the Border Regiment: Surgeon-Captain W. B. Cockill is borne as Supernumerary whilst commanding the Lancaster and Border Volunteer Infantry Brigade Bearer Company (dated Nov. 7th, 1903). 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment: Surgeon-Lieutenant-Colonel J. W. Martin resigns his commission with permission to retain his rank and to wear the uniform of the battalion on retirement (dated Nov. 7th, 1903); William Smith Kerr to be Surgeon-Lieutenant (dated Nov. 7th, 1903).

DEATHS IN THE SERVICES.

Surgeon-Major-General James Davis, Army Medical Staff (retired), at his residence at Southsea on Nov. 8th, aged 68 years. He entered the army as assistant surgeon in 1858, served with the 57th Regiment in the New Zealand war in 1861, and was present at the repulse of the attack on Camp Nukumaru and in the engagement at Kakaramea. He became surgeon-major in 1873, surgeon-major general in 1894, and retired in the following year.

"Audi alteram partem."

THE FUTURE OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—The present position of the controversy regarding the provision of an adequate scheme for the reconstruction of St. Bartholomew's Hospital is well calculated to cause widespread anxiety and disgust. The official proposals include an appeal to the public for a sum of £350,000—an appeal which obviously must fail unless the public judgment is first convinced. At the same time experts who speak with authority denounce the official scheme as seriously defective in respect both to present demands and future development. It is pointed out, for example, that the received plans include such a highly objectionable feature as the retention for the reception and treatment of in-patients of buildings which have been used for this purpose for at least 150 years and in which it is impossible to obtain a proper supply of sunlight and fresh air. Further, the hygienic condition of the hospital will be made dangerous by adding an additional storey to the north wing and by crowding an already crowded site with many additional buildings. The scheme, in short, instead of representing the highest level of hospital construction and sanitary efficiency, will merely put a modern gloss on old faults and will provide a hospital having grave and essential defects. The corollary is inevitable—that the future St. Bartholomew's Hospital will be promptly recognised as an exhibition of the folly of half measures and that its decline in public and professional estimation is certain. This, in essence, is the criticism passed by responsible voices on the plan of the Mansion House Committee now before the public for the reconstruction of a hospital the premier position of which in relation both to historical associations and practical achievement is recognised in all parts of the empire. This fact alone is sufficient to show that the scheme is foredoomed to failure. For efficiency the public sympathy may readily be enlisted, but it has no voice or help for a policy of shreds and patches.

Criticism in the present instance, however, has not merely a destructive aspect. On the contrary, it propounds an alternative scheme which, if adopted, will secure for the hospital everything that modern experts advise and will at the same time guarantee the opportunity for such developments as are probable in the future, the estimated outlay here being a sum of £600,000. These, in brief, are the rival policies presented to the public and it needs no special gift of discernment to anticipate that the more radical proposal is the more likely to attract interest and support. St. Bartholomew's Hospital has a wide and well-deserved fame. Its traditions of efficiency and success may be traced through the medical history of 800 years. From its walls have issued for generations countless numbers who in all parts of the world have practised the art of healing. Its physicians and surgeons include the many names which are the cherished heritage of the profession. Enthusiasm on behalf of such an institution only waits to be aroused. There now exists an opportunity to add to the noble history of the past the developed efficiency which the modern spirit requires. Is it reasonable to believe that energy will awake on behalf of a proposal to meet this opportunity with half-hearted and temporising measures? Certainly it may be taken for granted that the controversies of the last 12 months have developed in the public a feeling of hesitation and doubt and that the more recent criticisms command a degree of confidence which official silence will altogether fail to disturb. Before they offer their support the public will insist on knowing all the facts.

In this respect one of the most remarkable features in this prolonged controversy has been the absence of any expression of opinion by the medical staff of the hospital. Doubtless the views of the staff were officially submitted to the Mansion House Committee but they have never reached either the governors of the hospital or the general public. The responsibility of the staff in this matter is a considerable one. They are in a very special sense aware of the existing defects in the hospital. They are also aware of the changes necessary to remedy these defects. Further, it rests with them to estimate the probable future demands both of hospital treatment and medical education. Their judgment and decision on these points must necessarily carry substantial weight and in the essential interests of the hospital it is imperative that their opinions should be publicly pronounced. With them in a large measure rests the decision whether "Bart.'s" shall continue and enlarge its noble history or shall dwindle into a second- or third-rate position among the medical institutions of the metropolis.

Public opinion will certainly demand that London shall have at least one modern hospital and medical school replete in every respect. The inclination of the City and, indeed, of all parts of the country, is to support the position and claim of St. Bartholomew's Hospital. But there are other candidates and their virtues will not be neglected on merely sentimental considerations. It is only an efficient programme which will secure public support. There are rumours afloat that the silence of the hospital staff is due to a fear of offending one or more august patrons of the hospital. Considering that the most distinguished personage in the realm and his royal son have both identified themselves with a policy of hospital thoroughness and efficiency these rumours may be neglected. In any event the claim for a clear statement is imposed by the sanction of duty. It rests with the staff to satisfy public opinion and in the absence of this the financial success of any scheme is more than doubtful. They have still another opportunity. "Bart.'s" men, proud of their *alma mater*, are to be found in influential positions all over the world. A courageous appeal from the present staff, accompanied by the assurance that the future of the hospital and school is at stake, would go a long way to raise the money necessary for a complete reconstruction. The precedent of "Guy's" is a full justification for this statement. But so long as the medical staff stand silent so long will there be doubt and mistrust and the public will remain aloof. The opportunity for a large and worthy success now exists. Is it to be lost through a faint-hearted and short-sighted policy backed by the supineness of the medical staff and old "Bart.'s" men all over the country? I cannot believe it.

I am organising a definite, purposeful, and sustained opposition to the scheme of the Mansion House Committee, which, if persisted in, must ultimately ruin St. Bartholomew's Hospital. I am a governor of St. Bartholomew's Hospital and although the fight will be earnestly maintained by us laymen the continued silence of the medical staff must render a difficult task doubly difficult. If it be true that the medical council made representations to the treasurer before the meeting of the governors on Nov. 5th to the effect that the site must be larger and that the wards for the reception of patients must be entirely modern and up to date that report has been kept back from the governors. We ought, however, to know the facts.

I am, Sirs, yours obediently,

ANDREW MOTION,

Chairman of the Cannon Brewery Co., Clerkenwell, E.C.

Banbury, Nov. 10th, 1903.

*** Mr. Motion is evidently not aware of the action which the medical staff has taken in this matter for some years. Being a governor of the hospital he surely could obtain access to the various reports on the subject which the medical staff has sent to the authorities. The views of the staff were published substantially in the columns of THE LANCET a fortnight ago.—ED. L.

THE UNIVERSITY OF LONDON AND THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—There seems to occur a primary sense of perplexity about introducing the new final State's examination or Doctorate in Medicine in the proposed Medical Acts Amendment Bill, but clearly the rights of the older corporate examining bodies cannot be annulled without negotiations which have not taken place, and, besides, there are the difficulties of authority where we, unfortunately perhaps, have not got State control of, nor a State Minister of, education. Meanwhile the worried London student of medicine is still left ding-donging at the final Hall, then the final Colleges, then the final M.B., then the final Fellowship examinations, and even then will not obtain the expected or desired *University* M D, a unique and silly arrangement compared with any other part of the civilised world This shows the necessity of reform With regard to any complete proposal, before endeavouring to bring the great medical bodies and the standard medical teaching interests in London together, it is essential to bear in mind that all the commissions and schemes dealing with this question, and including the Jenner suggestions in 1885, were absolutely discarded in favour of *the reform of the University of London So, evidently*, the University of London Act 1898, alone shows at the crest of practical politics Now, it happens that the present petition of the London Licentiates and Members' Society to the University of London is entirely founded on the Jenner proposals, yet it goes, not again to the Royal Colleges where the same petition has been rejected, but to the University, and it claims simply an immediate entrance to a retrospective degree for all old London Conjoint men There is ample reason, even if it were hoped otherwise, for the University to object to such an intrusion, it would at least expect the Royal Colleges to make the first move

What is much more important for the welfare and medical interests of London, and what most people wish to see accomplished, is the joining on mutual terms of advantage of the ancient Royal Colleges of Physicians of London and Surgeons of England with the new and, perhaps, more intellectual University of London or at least as far as its examinations go This can perfectly easily be done under the Charter Act of 1898 Section 4 and Statutes 119 and 123. The same courses of lectures could be arranged and slight adjustments made in the closely similar examinations, which would end in giving London medical students a proper standing for the actual work to be done What is wanted is one compact, and representative medical faculty in the University, appealing to London and popular support.

It is most impolitic to debar capacity for the higher positions in the medical profession to the holders of the diplomas The diplomates cannot do better than their training or their opportunity allows them, and the fact that they have started for the "*licence*" standard spoils their whole career down to the grave If all started in the University the grossly unfair handicapping would be done away with *The disabilities of the Licentiates and Members of the Royal* Colleges are well known and they need not be recapitulated, it is little short of a scandal to continue a state of affairs which precludes diplomates from D P H work and house appointments simply because their title is not the current title of the day The London position is behind that of other nations, in America and in Paris they have long since consolidated their colleges with the universities, and that is what the proposed union between the University of London and the Royal Colleges should insist on

It may be interesting to note how nearly this reform took shape in the first part of last century Before and after the foundation of the examining University of London in 1836—the University of London was founded in 1825—the medical students of the Royal Colleges flocked to the University doubtless on the understanding that a "*degree*" course was intended, but in 1866 the numbers quite characteristically dwindled to 163—from 494 in 1839—when it became clear that both bodies had set up a selfish fiscal policy of their own and so stopped this imminent advance and progress From the first the notion to amalgamate with all the medical interests in the metropolis was probably the best and most conspicuous object *in the promotion of London University, that policy* at the first meetings was subscribed to by Lord Dudley, Lord Lansdowne, Lord Brougham, Lord John Russell, the Duke of Norfolk, and Campbell, Grote, James Stuart Mill and John Stuart Mill, which, it must be said indicated powerful support We have the same obligations to our own generation still before us The diplomates of the Colleges ought to act, either with or without the aid of a society, so as to help the councils of their Colleges to initiate and to bring about the movement for unity which has exercised for long some of the highest thinkers in the University as well as in the College Councils In that way the occupation of the Royal Colleges of Physicians of London and Surgeons of England from gradually but inevitably vanishing may be stopped If there be no action for unity taken and the arena of the annual College meetings be alone left for discussion of such matters our precious opportunities will somnolently and smoothly drift from one decade into another and the result will be inevitable

I am, Sirs, yours faithfully,

Bognor Oct 31st 1903 H ELLIOT BLAKE

RECURRENT OVARIAN CYSTOMA AND ABERRANT ACCESSORY OVARIAN STRUCTURES

To the Editors of THE LANCET

SIRS,—The explanation given by Mr J D Malcolm[1] of recurrent ovarian cystoma of pregnancy after the surgical removal of both ovaries or their destruction by disease, and of other kindred conditions, seems to me to leave something to be desired I am prepared to admit that some instances of this kind may be ascribed to the retention of fragments of healthy or diseased ovarian tissue detached at the first operation, but I believe that the majority of such incidents cannot be accounted for in this way Cases of this kind are known to have occurred even after the most radical operations, involving the extirpation *en masse* of the uterus, ovaries, and adnexa when it is highly improbable that any fragments of the ovaries could possibly have been left behind Even if the presence of aberrant accessory ovarian structures in the pelvic connective tissue and its vicinity had never been actually demonstrated, I maintain that it would nevertheless be possible for one who had made himself thoroughly acquainted with the *ensemble* of facts relating to conditions of this kind, to predicate that such aberrant structures do exist and that their presence is the cause of most of these curious phenomena

When Cohnheim first announced his celebrated theory of the origin of tumours from sequestrated fragments of the germinating tissues, very few facts could be adduced in support of it No one then believed in the possibility of such an amount of developmental irregularity as it presupposed The light of modern science has, however, effectually dissipated this misconception, and our eyes have been opened to the hidden defects of normality Sequestrated fragments of the various tissues and organs have now been found to exist in every part of the body that has been specially examined for them The ovary is no exception *to this rule, although gynæcologists* have hitherto hardly realised this important fact and its significance

Although a thorough search, with the best modern appliances, for accessory ovarian structures in the pelvis and its vicinity has not yet been made yet enough is already known to justify me in stating that these structures like tuberculous foci in the lungs are nearly always present Even as long ago as 1878 Beigel, with only the crudest methods found accessory ovarian structures in 23 out of 500 necropsies, and since then numerous instances of this kind have been reported (Thumin Seitz, and others) These structures are commonest in the immediate vicinity of the ovary, to which they are sometimes attached by a fine stalk As many as six have been demonstrated close to a single ovary De Sinéty has met with the condition in a newly born infant Probably most sessile so called ovarian cysts arise from these structures But accessory ovarian structures have also been found in situations much more remote from the ovary Beigel long ago demonstrated their presence in the broad ligament and many other instances have since been reported It is to this source that the various ovarian like tumours that have from time to time been met with in the broad ligament and its vicinity may be ascribed (Vautrin, Terraillon Brigidi, and others) Many so called "migrated ovarian tumours no doubt belong to this category Lefas discovered an aberrant ovarian structure which comprised a fully developed corpus luteum, connected with one of the fimbriæ of the Fallopian tube and Thumin has described an ovarian cyst which arose from a structure of this kind. Seitz and others have shown that these aberrant structures may occupy an intra or extra peritoneal position Many instances have been recorded of ovarian like cystomata arising primarily in para uterine, paravaginal and paravesical regions in the round ligaments, and even in the lower part of the abdomen quite outside the *peritoneum (Fergusson Meredith,* Olshausen Kaltenbach, Winternitz, Hartz, Krönig, Coblenz and others), which could hardly have had any other origin than aberrant ovarian structures. Dermoid elements and traces of Wolffian rests may be associated with these tumours. The presence of aberrant structures of this kind in various parts of the pelvis and its vicinity, enable us to understand the occurrence of recurrent ovarian cystomata and of the other curious phenomena above mentioned. What is the condition of such structures after the removal of both ovaries? We know that they are then exposed to the stress of enormous formative activity—the so-called compensatory hypertrophy. In these circumstances the limits of physiological activity may easily be overpassed, and when the process becomes pathological it eventuates in the formation either of non-malignant cystoma or of a malignant tumour. Thus may be explained the extraordinary frequency of malignant disease after the removal of both ovaries, to which I have elsewhere called special attention.—I am, Sirs, yours faithfully,

---

[1] THE LANCET, Oct 31st, 1903, p 1227

Clifton, Bristol, Nov. 2nd, 1903. W. ROGER WILLIAMS.

EROSIVE GASTRIC ULCERATION.

To the Editors of THE LANCET.

SIRS,—In April, 1902, I exhibited at the Kidderminster Medical Society a girl upon whom I had successfully operated for gastric erosion. The notes of the case were given in your report of the meeting in THE LANCET of April 26th, 1902, p. 1185. I was very much interested to read the case published by my friends Sir Dyce Duckworth and Mr. H. T. Butlin and also your annotation thereon in your issue of Oct. 17th. I thought that it might be interesting to your readers to know that I am able to state that the patient has had no return of her symptoms.

I am, Sirs, yours faithfully,
J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.
Oct. 20th, 1903.

THE *DE NOVO* ORIGIN OF BACTERIA.

To the Editors of THE LANCET.

SIRS,—In the course of his paper on the *De Novo* Origin of Bacteria in THE LANCET of Oct. 31st, p. 1220, Dr. H. Charlton Bastian refers to a signed article of mine on Leprosy which appeared in the *Quarterly Review* for April, 1903, and from which he quotes. He contends that the verdict given by the Leprosy Commissioners in their report (Calcutta, 1893) was perfectly logical and quite explicable in accordance with known facts. I hope you will allow me to quote a little more at large from my article. I wrote: "Some years ago the Royal College of Physicians of London, in a report on the Mode of Origin and Spread of Leprosy, unfortunately expressed the opinion that it was not contagious. More recently the Leprosy Commissioners in India came to the conclusion that the infectious nature of the disease had been finally established by the discovery of the bacillus and stated 'that the disease was to be classed among the contagious diseases, the influence of contagion being as small as, or even rather less than, in the case of tuberculosis.' They also concluded there was no evidence that leprosy in India was hereditarily transmitted from parent to child and, further, that neither the form of diet nor the sanitary environment of the individual had any specific action in the causation of leprosy. At the same time, the Commissioners added that 'it is probable that bad hygienic surroundings, deficient or improper food, poverty, exposure, and such diseases as syphilis are all factors of great importance in reducing the vital powers of the organism and rendering it more susceptible to attack.' The evidence pointed inevitably to the conclusion that leprosy is an infective contagious disease. But strangely enough, the Commissioners in their final summing up expressed the opinion that leprosy, in the great majority of cases, originated *de novo*. A critic has well said that this conclusion was extraordinary and contrary to the experience of those who had given special attention to the subject in leprous countries. It was all the more extraordinary, I added, seeing that the Commissioners advocated voluntary isolation. Further on in their report the Commissioners remark that both leprosy and tuberculosis are contagious in an equal and minimal degree." I leave it to the reader to judge for himself as to the logic of such reasoning. I would recommend him to read the report of the Leprosy Commission, and also, if I may venture to say so, my *Quarterly Review* article, wherein he will find a succinct survey of leprosy as a whole.

I regret that Dr. Bastian should consider my attitude in the matter intolerant because it clashes with his views on the *de novo* origin of various diseases. I quite thought the *de novo* theory had gone by the board long ago. I regret it all the more as Dr. Charlton Bastian was one of my clinical teachers at University College Hospital. I learnt from him important facts at the bedside, for which I am ready to express my indebtedness. On the other hand, I cannot allow my esteem for him to stifle my own honest beliefs on certain points.—I am, Sirs, yours faithfully,

GEORGE PERNET,
Assistant to the Ski[illegible] College Hospital;
Upper Gloucester-place, N.W., N[illegible]

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

To the Editors of THE LANCET.

SIRS,—May we be permitted as president and officers of the Society of Medical Phonographers to bring the continued existence of the society and its usefulness under the notice of any practitioners or students of medicine who make use of shorthand? Of late the society has not come much under the notice of the profession, but its work continues. Its organ, the *Phonographic Medical Record*, is published monthly and affords the means of obtaining familiarity with medical shorthand, together with definite information on practical medical subjects. The society has also issued a series of small original works in lithographed shorthand with the same object, as well as an extensive vocabulary of convenient outlines and guides to the use of shorthand both by the student and the practitioner. It has also held periodical examinations for students in order to encourage their acquisition and use of shorthand.

The invaluable aid which it can give in medical work, practical and theoretical, in case-taking and note-making, is realised by all who have used it, as it cannot be by others, and the importance of its acquisition before medical studies are commenced is so great that the society has endeavoured by every means to encourage this. But many practitioners who make constant use of shorthand have acquired it long after being engaged in practice. To all, students and practitioners alike, the society is open and its members are ready to give all possible help to those who are endeavouring to obtain the assistance of this time-saving art. The subscription to the society is very small, amounting only to 5*s.* per year for students and 7*s.* 6*d.* for practitioners. The honorary secretary, Dr. Fletcher Beach, will be glad to give any further information and to receive applications for membership.

We are, Sirs, yours faithfully,
DAVID FERRIER, President
E. B. GRAY, W. THOMSON, C.B., Vice-Presidents.
W. R. GOWERS, G. SIMS WOODHEAD, Members of Council
NORMAN PORRITT, Treasurer.
FLETCHER BEACH, Secretary,
Winchester House, Kingston-hill, Surrey
Nov. 6th, 1903.

THE RELATION BETWEEN THE SIZE OF THE CHILD AND THAT OF THE PELVIS.

To the Editors of THE LANCET.

SIRS,—The perusal of the leading article in THE LANCET of Oct. 3rd, p. 963, in which you comment on my paper published in the issue of Sept. 26th, p. 885, makes it plain that I have so expressed myself as to appear to claim more for the law I enunciated than I had any intention of doing. I do not seem to have made the heading clear. You remark that I enunciate a "law by which the size of the child is to be determined." What I wrote was "a law by which the size of the child is determined." The former appears to imply a process by which a man may infer the size of the child in a particular case from that of the mother's pelvis; the latter was intended to draw attention to an orderly working of nature in the average.

In the light of your comments it is evident that the fact that I have made no attempt to establish in any degree the relative effect that different causes have in determining the size of the child will lead the reader to suppose that I do not consider the usually accepted ones as potent. This is very far from being the case and the omission to lay stress on these is due to the fact that opportunity to sift such figures as I have accumulated has hitherto been lacking. It is very far from my intention to put forward this law of parallel growth as the only factor determining the size of the child; it is undoubtedly only one of several, but it is one which has hitherto escaped attention but yet merits further investigation, and it is partly for this very reason that I have published the figures, for being no longer in a position to carry on this investigation myself I wish to bring it to the notice of others for confirmation or refutation. You further criticise my paper in two directions—first, as regards facts and, secondly, as regards the inferences to be drawn from them. The facts you object to, first, on the score of the insufficiency of the measurements. The cases are 111 in number and certainly before such a law as I have stated is allowed generally the figures available will have to be much greater; at the same time I think that the very regularity of the parallelism between the size of the conjugate and that of the child is a warranty that further numbers will confirm those given.

You are disposed to think that my figures are not accurate *and that accurate figures could only be obtained either by* examination on the cadaver or under anæsthesia. Undoubtedly measurements on the cadaver would be most useful, but their accumulation would take very much longer than the accumulation of clinical figures. I do not consider that the condition of anæsthesia would make results more accurate because the recti have usually little influence ten days after delivery in the ease with which the promontory is reached. The muscles are usually still separated and the hand can sink between them without serious resistance. You are further of opinion that it is impossible clinically to estimate the size of the conjugate diameter of the pelvis accurately within a quarter of an inch. This is probably true in any individual case but I think that by taking many measurements the results will be accurate in the average. Even if this conclusion is not correct, it will yet be found that the figures for successive increase of half an inch in the conjugate *diameter, concerning the general accuracy of* which there can scarcely be any question, are just as striking and as strong evidence of the law which I have put forward.

My conclusions are drawn from averages. That the parallelism of the child and the pelvis is one of average is constantly insisted on in all the tables accompanying the paper and it will not necessarily hold in individual cases except within wide limits. In order to avoid making the paper too long no lists of actual figures were given. As an example of the differences in these I may say that taking the Bengalis with a pelvis estimated at between four and four and a quarter inches in the conjugate diameter the weight of the children varied from four pounds 14 ounces to eight pounds six ounces. This in itself is sufficient proof that other factors than that of the size of the pelvis are concerned in regulating the size of the child and that the size of the latter can only be estimated within wide limits from that of the former. I do not wish to claim that the law which I have enunciated is the only or even the chief law by which the size of the child is determined; but subject to confirmation or refutation I hold that it is a factor, a practically unrecognised factor, and one the relative place of which among the others requires investigation which I am not in a position *to carry out myself.*

Your objection that normally sized children may be born through a congenitally contracted pelvis need not, I think, invalidate the general law. Other congenital factors may have been stronger and have *resulted in* the production of a normally sized child. The consideration of the relative influence of these various factors in determining the size of the child, so far as I have figures on which to base conclusions, I have intentionally omitted from my paper and my apparent dogmatism has been due not to any want of appreciation of the importance of these but partly to the wish to emphasise the new factor and partly to the hope that I should find opportunity in the future to sift the evidence satisfactorily.

I am, Sirs, yours faithfully,
CLAYTON LANE, M.D. Lond.,
Captain, I.M.S.
Medical College, Calcutta, Oct. 20th, 1903.

THE M.D. DEGREE OF BRUSSELS.

To the Editors of THE LANCET.

SIRS,—If Dr. N. Leonard will refer the question of the value of the M.D. Brux. to the proper official quarter in Brussels he will find that my statement in THE LANCET of Oct. 17th, p. 1119, is absolutely correct—viz., that the degree does *not* confer the right to practise in Belgium and that the examination is quite a different one from that which the Belgians themselves undergo. A few foreign medical men were formerly authorized to practise a *speciality* in Brussels irrespective of the particular qualifications they held—though similar favours are not now granted. This, I presume, is what Dr. Leonard refers to in his last paragraph in your issue of Oct. 24th. I think if these facts were more widely known fewer Englishmen would be ready to take a degree which is valueless even in the country where it is obtained.

I am, Sirs, yours faithfully,
Ludgate-hill, E.C., Nov. 5th, 1903. P. A. NIGHTINGALE.

SIMPLE CYST OF THE LIVER.

To the Editors of THE LANCET.

SIRS,—Attention having been called to the rarity of simple cysts of the liver in the paper by Mr. Alban Doran in THE LANCET of Oct. 31st, p. 1218, I think it worth while to refer very briefly to one case of my own. I knew at the time I operated on the case that it was a rare one but after reading Mr. Doran's paper it seems to me desirable that it should be recorded.

A woman, aged 63 years, came under my care in hospital in November, 1900, with a smooth round swelling in exactly the position of a distended gall-bladder. She had no symptoms and had noticed the swelling (which was visible) accidentally two months before I saw her. On opening the abdomen I found the whole liver enlarged so that the lower border of the liver reached nearly to the umbilicus, and projecting from it a bluish translucent cyst of the size of an orange. There was no liver tissue on its anterior aspect but it did not quite extend through the substance of the liver below—i.e., it lay above the quadrate lobe. Its wall was very thin, white, and glistening and it contained straw-coloured fluid. It did not in the least resemble hydatid cyst. The gall-bladder was hidden away under adherent colon and omentum. I stitched the cyst wall to the parietal peritoneum and drained it and she made a good recovery.

I am, Sirs, yours faithfully,
Bristol, Nov. 6th, 1903 CHARLES A. MORTON.

ROBERT STEPHENSON AND THE PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—In these days when we think as little of getting into a train for a short or long journey as we do of eating our breakfast or going to church on Sunday it is perhaps somewhat difficult to cast our minds back to the time when George Stephenson constructed and carried through the first railway for passenger and goods traffic that the world has ever known. In the surveying of "The Stockton and Darlington Railway" George Stephenson was greatly assisted by his only son Robert, to whom England owes much as a pioneer in railway enterprise, after having paid due homage to his truly illustrious father. The centenary of Robert Stephenson has recently occurred, for he was born on Oct. 16th, 1803, and in these days when centenary anniversaries are taken as fitting occasions for the recognition of lives that have been spent in the service of their country it seems unjust that a life so well spent and of such practical service not only to Great Britain but to the whole world should be passed by without comment of any description.

When we consider how dependant we are on our railways and other engineering projects, how the health of dwellers in towns is often speedily restored at perhaps a minimum of time and expense by a quick journey to the country or seaside for rest and change of air and scene, when we think also how the congested state of our towns can at any time be relieved and how at the same time the ambitious villager can satisfy his curiosity about town-life and progress by journeying from one place to another, the general public and the medical profession with it can only recall with gratitude the names of those benefactors who have helped, even indirectly, to increase the standard of health in our country and consequently the happiness of the individual. The landmark, therefore, that draws attention to the birth of one of such men can hardly be allowed to pass by unobserved and the name of Robert Stephenson should be again revived and remembered for that ability, perseverance, and industry that have contributed so much to the increased comfort of life and thus been of such inestimable benefit to the public at large. I am, Sirs, yours faithfully,

T. Wilson Parry, M.A., M.B., B C. Camb.

Highgate, N., Nov 9th, 1903.

THE NEW REGULATIONS FOR THE INDIAN MEDICAL SERVICE.

To the Editors of The Lancet.

Sirs,—The text of the new memorandum regarding the Indian Medical Service published in The Lancet of Oct. 3rd, p. 973, and your special article commenting on its provisions sufficiently show that the Secretary of State and his advisers may be sincerely congratulated on the issue of the document, though much still remains to be accomplished and not a little to be explained.

The date of the memorandum is October, 1903, and although the heading of the memorandum would make it to appear that the advantages announced are prospective, yet I cannot help thinking that the wording is at fault and that these advantages are also to be retrospective and that they will apply to the officers now holding commissions. It is a wise departure from an old rule that no promotion examinations should obtain in the Indian Medical Service, that lieutenants after completing 18 months' service and before promotion to the rank of captain will be required to pass an examination in military law and in military medical organisation. I read that the result of this examination may affect an officer's promotion —this statement would have been more useful and better liked had it been accompanied by some explanation of the possibilities attached to such an examination. Is the result of this examination to carry the privilege of accelerated promotion or is failure to pass it merely to retard promotion to captain's rank? and is such retardation to be temporary only or to carry with it a permanent forfeit of position in the Army List? These are the questions which men are now asking.

Section 16, which deals with the "pay and allowances," has evidently been the subject of much earnest attention The gains to the service which are announced are substantial, as the appended table clearly sets forth, in which I have compared the old and new rates of pay.

Rank.	Unemployed pay.		Grade pay.	Staff pay.	In officiating medical charge of a regiment.		In permanent medical charge of a regiment.	
	Old rules.	New rules.			Old rules, minimum.	New rules.	Old rules.	New rules.
	Rs.	Rs.	Rs.	Rs.	Rs.	Rs.	Rs.	Rs.
Lieutenant	350	420	350	150	400	425	450	500
Captain...	350	475	400	150	400	475	450	550
,, after five years' service	450	475	450	150	500	525	600	600
,, after seven years' service	450	*	500	150	500	575	600	650
,, after ten years' service	500	*	550	150	550	625	600	700
Major	640	*	650	150	—	725	800	800
,, after 15 years' service	677	*	750	150	—	825	800	900
Lieutenant Colonel	852	*	900	350	—	1075	1000	1250
,, ,, after 25 years' service	888	*	900	400	—	1100	1000	1300
,, ,, specially selected for increased pay	900	*	1000	400	—	1200	1100	1400

*Grade pay.

The minimum sum which a lieutenant can now receive after arrival in India is Rs. 420 a month, the equivalent, with the exchange compensation, of £357 a year; while the officer who never aspires to anything beyond the charge of a regiment and who serves for over 25 years will in future draw Rs 1300 a month, which is equivalent to over £1100 a year. To these rates of pay every man who enters the Indian Medical Service may confidently look forward, for paragraph 9 states that "a major is promoted to lieutenant-colonel on completion of 20 years' full pay service"—there is to be no selection for that rank to which every officer, as heretofore, who serves long enough will attain. It will be noted that the "grade pay" and "staff pay" taken together are the equivalent of the pay and allowances for the permanent medical charge of a regiment. We are told that "staff pay" is the pay of a "command" and is drawn in addition to grade pay. What the word "command" will be deemed to signify is not clear but it will no doubt have a wide significance and be applicable to all military medical appointments which are not connected with the medical charge of a regiment.

There are certain circumstances other than those pointed out in your article in which the memorandum may be a disappointment to the service. You rightly comment on the absurdity of saying that men can enter the service up to the age of 28 years and at the same time informing them that the maximum pension is not open to them. As a rule the men who enter the service after 25 years of age are those who have spent additional time in study, in resident hospital posts, and in the junior teaching appointments in the schools, and such men ought to be encouraged in every way, while under the present rules they are almost debarred from the highest rate of the ordinary pension; but it is a real pity also that nothing has been done to increase the rates of temporary and permanent half-pay for those who break down in India and are really incapacited. Many of the captains in the service are married and the sum of £127 15*s*, the rate of permanent half-pay accorded to them, is very small. All of us know of cases where men have been so broken down by the Indian climate that they have been forced to retire on this pittance and in a condition where work in private practice in this country is not possible to them. The rates of half-pay are less than those offered to the officers of the Royal Army Medical Corps and they stand in need of revision.

From your comments on the conditions of civil employment it might be supposed that no improvement in the pay of the officers in civil employment has been contemplated. May I, however, point out that the pay of an officer in substantive charge of a first-class civil station has always been Rs.50 a month more than the pay for the charge of a native regiment and that the pay for the substantive charge of a second-class civil station has always been Rs. 50 a month less than the pay of an officer in permanent charge of a regiment, so that the increase of pay on the military side of the service naturally infers an equal increase for those officers who prefer to work in civil appointments. Now that the chances of private practice are so much less than formerly the pay of a civil surgeon of the second class should be increased so as to be at least equal to that of an officer in regimental employment.

In conclusion, although there are directions in which the memorandum fails to redress obvious grievances, as you rightly indicate in your comments, the additions to pay and pension and the other privileges announced must go some way to render the Indian Medical Service as popular as it was some 20 years ago.—I am, Sirs, yours faithfully,

Veteran.

Nov. 6th, 1903.

TAYLOR'S "PRINCIPLES AND PRACTICE OF FORENSIC MEDICINE."

To the Editors of THE LANCET.

SIRS,—I have been requested by Messrs. Churchill to edit a new edition of Taylor's large work on the "Principles and Practice of Forensic Medicine." Might I appeal through your columns to the profession to send me accounts of interesting and instructive medico-legal cases that have been recently decided? Dr. Stevenson has with the greatest generosity and kindness placed at my disposal a rich collection of poisoning cases, so that I am more particularly anxious for other criminal reports, such as rape, strangulation, &c. Might I ask that dates and references to the trial should accompany any reports sent to me at this address?

I am, Sirs, yours faithfully,
138, Harley-street, W., Nov. 9th, 1903. FRED. J. SMITH.

SOME CASES OF DILATATION OF THE BRONCHIAL TUBES AFTER MEASLES.

To the Editors of THE LANCET.

SIRS,—I beg to call attention to the following slight error which has crept into the publication of my paper in THE LANCET of Oct. 31st. The words "the lungs" on the last line of the second column on p. 1225 should have been "*the lower lobes.*" By the way, the bronchial glands shown in Fig. 2 were not caseous. The enlargement was due to acute inflammation dependent upon the presence in the lung of broncho-pneumonia

I am, Sirs, yours faithfully,
THEODORE FISHER, M.D. Lond.
Clifton, Bristol, Nov. 9th, 1903.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—Transport for Invalids.—Medical Missions in India.

A SUDDEN upward leap has occurred in the plague mortality during the past week. After remaining at about 13,000 for two or three weeks it has now risen to 16,204, chiefly due to a recrudescence in the Bombay Presidency. The following figures show the local increases: Bombay Presidency, from 8868 to 10,890; Mysore State, from 554 to 627; the Punjab, from 80 to 425; Madras Presidency, from 146 to 185; United Provinces, from 95 to 120; Bengal, from 41 to 85; and Rajputana, from 33 to 52. Slight decreases have occurred in Central India, in the Hyderabad State, Bombay city, Kashmir, and Calcutta.

The transport *Plassey* has been specially fitted to convey to England 100 helpless invalids on each trip during the ensuing trooping season and the nurses required for duty will be drawn as far as possible from those nurses to whom leave to England is being granted. The nurses will receive full Indian pay during the voyage and their leave will date from their arrival in England.

The Medical Missions in India seem to be doing a good work. There are over 76 mission hospitals and over 100 dispensaries and they are all under the care of fully qualified practitioners. The Church Missionary Society has a group of medical missions in the north-west of India, of which the Kashmir branch has been particularly successful, but the Amritsar branch seems to be almost equally popular. In the south is the London Mission Society's branch in Travancore, which attracts very large numbers and is evidently highly respected. Then there are the hospitals maintained in Bombay, the United Provinces, and in Arcot by the Presbyterians; the hospitals in the Maratha country and in Madura, kept up by the Congregationalists; and the hospitals in Assam, the Telugu country, and Burmah, looked after by the Baptists. The Germans are represented by the Basel Mission in Malabar, and there are the Australasian Baptist Mission in Eastern Bengal and the Canadian Presbyterian Mission in Central India. Even the Salvation Army has its medical mission at Nagercoil, in Travancore, under a well-qualified graduate. There is no doubt that the medical part of these missions is supplying a long-felt want amongst the masses of the poor natives in India who in illness are otherwise at the mercy of ignorant quacks or without any assistance whatever. Judging from reports many of the officers must find plenty of work in strictly following their profession. The opportunities for practice are immense and embrace all branches of our profession.

Oct. 24th.

THE
ELEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE DIVISION OF DEMOGRAPHY.

Infantile Mortality.

THE seven sections of hygiene met, as already explained, in the various committee rooms of the two Houses of Parliament. This was very convenient as at Brussels the Senate and the House of Representatives are located in the same building. But there was not room for the division of demography so it was allotted the Palace of Academies where there was ample space. But this building is on the other side of the Park and is from ten minutes to a quarter of an hour's walk from the Houses of Parliament; it was not easy, therefore, for the members of the division of hygiene to go to the division of demography so that the two were more separated than was desirable. The members of the division of demography on their side had but little time to spare; for their programme was very overloaded. They had printed reports on no less than 14 different questions though only 12 resolutions were sent from the division to the general assembly of the entire Congress. On the first question Dr. J. F. W. Tatham, superintendent of statistics at the General Register Office, Somerset House, London, presented a report on Infantile Mortality in England which was brief and yet very complete and easy to grasp. The only difficulty in regard to this report is that in England no record is kept of stillbirths as is done on the continent. Thus, Dr. Guillaume, chief of the statistical bureau at Berne, was able to explain that since 1874 the law rendered obligatory the registration of all births at six months, whether still or living. By this means it had been ascertained that in Switzerland the proportion of stillbirths was equal to 4 per cent. of the total births. Dr. J. Wilmart of the Brussels bureau of hygiene gave a brief account of the law on the registration of births in all the countries of Europe and statistics relating to the same. For Brussels there are statistics not only in regard to stillbirths after six months but also of miscarriages before six months. Dr. J. Bertillon (France) thought that the deaths of infants were due to a special microbiology. Dr. Kiaer (Norway) urged that infantile mortality ought to be studied separately for each class of society. Dr. Presl (Austria) insisted that insufficient or unsuitable food was the principal cause of infantile mortality and in this he was supported by Dr. Maxweiller (Belgium). Dr. Kerstberg (Berlin) alluded to the very significant statistics drawn up at Berlin, which indicated the state of the weather and temperature as the principal cause of the high infantile death-rate, and Dr. G. von Mayr (Munich University) insisted that in Germany the infantile mortality had decreased though industrialism had increased. There were consequently other causes than the fact of the mother working in a factory or mill. M. Hector Denis, vice president of the division and professo [illegible] insisted [illegible] from th [illegible] problem [illegible] absolute. [illegible] cause of death details as to the social or economic position of the parents. It was particularly necessary to state whether the mother worked and at what trade. Finally the following motion was adopted:—

> [illegible] ortality is of great im- [illegible] the social condition of [illegible] themselves improve the [illegible] es expresses the desire [illegible] ministrative ordinances [illegible] g premature births and

stillbirths) so that all births should be registered together with their accessory circumstances. It would be the duty of statisticians, acting in agreement with the medical practitioners, to examine the lists of these births, so as to obtain uniform records of stillbirths and premature births.

The General Death-rates.

After thus dealing with infantile mortality the division of demography took in hand a number of reports on general mortality. Of course the main object is to obtain international uniformity in the method of recording deaths, their causes, and other essential facts. The chief difficulty, according to M. E. NICOLAI, who represented the Belgian Ministry of the Interior, was due to the rules in regard to professional secrecy. He thought that the receiving of death certificates should be concentrated in the hands of one authority instead of being left to local authorities.

Dr. DE MARTEAU (Belgium) did not think that such centralisation was possible nor could he approve of anonymous declarations. Professional secrecy was well in its way but it should not be placed above the interests of humanity.

Dr. BERTILLON thought that it would be very difficult to obtain a uniform nomenclature of the causes of death. A proposal to that effect was made at the Congress held in Brussels in 1853. In 1900 at the Paris Congress a new nomenclature was introduced but it was not yet universally adopted. Nevertheless it had served to show, for instance, the extreme scarcity of typhoid fever in Germany, while at the same time it demonstrated that in Spain 130 persons per 1000 of the population contracted that disease. Small-pox had caused only one single death in Germany during the last two years, though at Marseilles, Toulon, and in the large Spanish and American towns there had been many deaths from that disease. On the other hand, in Germany 22 out of every 1000 inhabitants died from measles and this was a larger proportion than in most of the other countries. The places which suffered most from all kinds of maladies were the American towns of Pittsburg and Alleghany. Ghent and Brussels suffered most from whooping-cough and Paris from diphtheria. At Havre and Rouen, where alcoholism was very prevalent, there were more deaths from tuberculosis than in any other part of France. There was but little cancer in America and in Spain; it was in Germany and the industrial towns of France that this disease was most prevalent. Dr. Bertillon explained that these comparisons had been rendered possible by the action of M. Delcassé, the Minister for Foreign Affairs of the French Republic. In 1900 M. Delcassé had brought together the representatives of 26 States and they drew up a convention requesting that a uniform nomenclature should be adopted (the Bertillon nomenclature). This was accepted by the United States of America and at their suggestion it was to be modified, if necessary, once every ten years. There were three sets of papers to be filled. The first contained the fullest details, the second was abbreviated, and the third was very short. The progress of this nomenclature had been most encouraging, for it was now applied to populations numbering in all 121,000,000 persons.

M. NICOLAI proposed, and the division adopted, the following motion:—

> The law prescribing the verification of all deaths by a medical officer appointed for that purpose by the local authority should be effectively applied. A law to this effect should be enacted where it does not already exist. A law should be adopted compelling medical men to notify to their Government the cause of all the deaths that occur among their patients. Pending the adoption of legislative measures in this sense an anonymous declaration of all causes of death should be made and this should be done in a manner similar to that prevailing in Switzerland.

The Birth-rates.

The questions relating to birth-rates were hurried over and the division adopted the following motion:—

> To give a statistical analysis of demographical figures these should be subdivided into homogeneous groups. To constitute these groups it is necessary that multifarious details should be supplied. In drawing up certificates and in the classification of statistics based on these documents relating to the civic position of individuals, it is desirable that the details of information given should be increased so as to facilitate the formation of the above mentioned homogeneous groups. The documents could further supply the elements of two important reports; one relating to the total fecundity of marriages determined at the moment of their dissolution, the other applicable to the annual fecundity as shown by the birth of children.

Statistics on Insanity.

Though not placed so early on the agenda the division then discussed statistics in regard to the prevalence of insanity. Dr. DE BOECK (Brussels) did not think that these were satisfactorily prepared as there was no proper record of the patients who were living with their families.—Dr A. MAHAIM (Lausanne University) thought that the Belgians were behind in their methods of the treatment of mental diseases and protested against the use of force. Naturally there were objections raised to these strictures but the division became harmonious again in the adoption of the following motion:—

> The Congress expresses the desire that statistics should be periodically prepared in all countries on the insane who are confined in asylums and those who are not confined. Such statistics should be drawn up even where it is only possible to obtain the figures relating to cases that have been notified to the public authority.

Statistics on Alcoholism.

The question of alcoholism was now discussed and it naturally awakened keen public interest. Dr. MAHAIM explained that Switzerland was one of the few countries where statistics as to the mortality attributable to alcoholism really existed. If the ordinary statistics were consulted it would appear that the deaths due to alcoholism amounted to 0·54 per 1000 in France; 2 60 in England; 2 36 in Norway; 3·83 in Belgium; and 6·25 in Sweden. But these figures in nowise corresponded with the consumption of alcohol in those countries. The fact was that in many instances only those who died from delirium tremens or while manifestly drunk were entered as deaths due to alcoholism. In Switzerland deaths indirectly due to alcoholism were chronicled. The result was that alcoholism was recognised as having killed in Switzerland as many people as typhoid fever or small-pox or diphtheria, that it was the most fatal cause of death after tuberculosis and pneumonia. It was quite as dangerous as the zymotic diseases and therefore arbitrary measures to prevent its spread were quite as justifiable.

Dr. BERTILLON, however, thought that statistics ought to give facts and not opinions. If a man died from cirrhosis the death must be entered as due to this cause, though the medical attendant might be quite right in deeming this to have resulted from alcoholism. Nevertheless, it was an opinion and they must only officially register facts. Opinions at best could be put in as marginal notes.

Dr. MAHAIM agreed with this and while recognising that the information required could not be looked upon as mathematically exact thought that it would nevertheless be instructive and interesting. The motions adopted on this question were as follows:—

> The Congress, recognising that heredity and alcoholism are among the most [illegible] efforts should be made to propa[illegible] riages with alcoholic persons o[illegible] in the production of insane offspring.
>
> The Congress considers that the only means by which Governments will at last be able to acquire a really precise knowledge of the danger of alcoholism and will be led to understand the necessity of adopting energetic measures is to provoke and to organise a vast statistical referendum in which the losses due to alcoholism would be minutely analysed. The division of demography asks that the form of such statistics shall be studied at the next congress.

Trade Diseases.

The rates of mortality in the different trades or industries were then discussed. The first object evidently should be to assimilate the statistics of the different countries dealing with the mortality in various trades so that the results might be compared and the information collected be of use internationally.

M. DENIS, reporter on this question, spoke at great length. He gave a full account of what the statistics collected in England had demonstrated and urged that the same classification should be adopted in all countries. He thought that the work accomplished by Dr. Bertillon would facilitate such unification.

Dr. VON MAYR pointed out that the benefit societies rendered great help in this respect and M. CAUDERLIER (an engineer of Brussels) insisted that the economic position of the workers should be stated side by side with the vital statistics. He insisted that in England the trades where the sanitary conditions were bad had been proved to produce the highest mortality.

Poverty and Pauperism.

Special statistics in regard to poverty were next taken under consideration. On this question M. DE LANNOY, delegate of the Belgian Ministry of Justice, was inclined to accept Mr. Seebohm Rowntree's "Standard of Poverty," though it seemed more like a certificate of chemical analyses than a picture of real life. He thought that wherever relief was given, whether by public or private charities, statistics should be drawn up. It was absolutely necessary that birth-rates and death-rates should be studied in conjunction with poverty rates. Such comparisons were much needed by the legislator. Following the example given by Mr Rowntree a minimum standard of living should be established for each country according to the cost in each locality of the necessities of existence. Those who had not money enough to live up to this minimum could be qualified as poor. But in Belgium the much easier task of recording in a systematic manner all the cases where relief was given had not been accomplished.

Dr. KIAER remarked that the period of life when there was the least poverty had also to be noted. People were not poor all the time.

A good deal of discussion ensued as to the possibility of obtaining trustworthy statistics on the prevalence of poverty and finally the division adopted a motion stating that:—

> The Congress considers that the practical utility of demographic [illegible] extremely useful to demography.

Statistics on Suicides.

M. DENIS *followed with his report on suicides* He had studied the manuscript reports at the Ministry of the Interior and the town-hall of Brussels and sought to show the social aspect of the causes of suicide. During the first six months of the year the number of suicides increased and they decreased during the last six months. But the *official statistics did not keep any record of the attempts* at suicide which from the sociological point of view were of equal importance. Men succeeded more frequently than women in killing themselves. They generally hanged themselves or employed firearms, while women preferred drowning. Widowhood was a very constant cause of suicide at Brussels. There was a distinct connexion between the density of population and the frequency of suicides. Economic conditions were of the greatest importance and there was always an excess of suicides at times of commercial depression.

Dr. VON MAYR insisted that suicides were more frequent in the spring which was the season of accentuated human activity Other speakers insisted on the desire of families to conceal the facts and the consequent difficulty of obtaining trustworthy statistics.

The Crowding into the Towns

Migrations, the depopulation of rural districts, and the increase of town populations formed the next subject discussed.

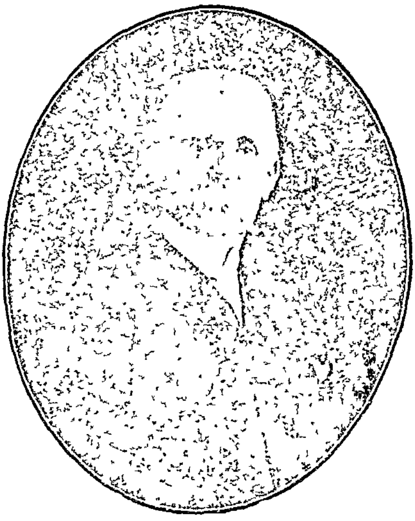
On this question M. NICOLAI, delegate from the Belgium Ministry of Public Instruction, presented a very lengthy report and many statistics In dealing with such a matter a great variety of causes had to be considered. In Belgium taking the average for the years 1890 to 1900 the birth-rate amounted to 29 65 per 1000 in the agricultural communes, to 29·30 in the industrial communes, and to 28 18 in the urban communes. In Belgium therefore the question of the depopulation of rural districts had not reached an acute stage. To this it was objected that though many men still lived in rural districts they went to work in neighbouring towns.

M. PAUL MEURIOT (France) presented a report explaining that it was the population of the suburbs of the large towns that showed the greatest increase and nowhere was this more alarming than in London. The outer ring of London now consisted of 149 additional parishes, covering 368,500 acres or 1491 square kilometres In 1861 this region had a population of 419,000, while the metropolis had a population of 2,803,000. Thus Greater London only contained 13 per cent. of the total combined population of metropolitan and Greater London. In 1881 this proportion had increased to 20 per cent but in 1901 the outer ring had 2,044,000 inhabitants, or 31·1 per cent. of the total. Thus the increase of population in the outer ring from 1861 to 1901 was 1,626,000, or 388 per cent, while the increase in the metropolis proper was 1,733,000, or only 61·9 per cent. 40 years ago there were 281 inhabitants to the square kilometre of the outer ring and to-day the same space had 1366 inhabitants In 1841 there were 12,738 inhabitants at West Ham and in 1901 they had increased to 267,308. The same could be said about other centres though the figures had not reached equally alarming proportions. In Paris there were 547,256 inhabitants in 1801 and outside Paris in the department of the Seine 84,052 inhabitants. In 1901 the figures had risen to 2,714,068 and 955,862 respectively. From 1881 to 1890 the increase of population in the four suburbs of St. Petersburg was equal to 18 7 per cent. It equalled during the ensuing ten years 140 6 per cent. The suburbs of Berlin only contained 6·7 per cent. of the total population in 1871 and they contained in 1900 no less than 27·9 per cent of the total. From these and many other similar figures M. Meuriot concluded that it no longer sufficed to consider the statistics of a large town unless the neighbouring districts or suburbs were included. Finally, it was generally agreed that the whole question of the migration of population, the overcrowding of urban districts, and the depopulation of rural districts needed further study and investigation. Therefore the discussion on these questions should [illegible]

The advant[illegible] and of creating a un[illegible]fly considered and a motion was adopted in favour of constituting an international bibliography on hygiene and demography. With this the labours of the division were brought to a close.

Final Excursions and Remarks.

Having now concluded the summary of the discussions held in the seven sections of hygiene and in the division of demography it is only necessary to add a few words of grateful acknowledgment to those who have helped me in this somewhat arduous task. The President of the Congress, M. Emile Beco, the general secretary, Dr Putzeys, and the secretary, Dr. Voituron, always rendered whatever assistance it was in their power to give The courtesy of these gentlemen made my task an agreeable one throughout and I am pleased to have an opportunity of publicly tendering them my best thanks. Nor should I conclude without saying a word about the excursions in which many members of the Congress participated after the Congress was over. The permanent deputation of the Provincial Council of Liège took some 200 members to visit the magnificent sanatorium which it has built at Borgoumont. Here there are 114 beds with 33 cubic metres of space for each bed, and the ventilation is so contrived that the air can be changed completely three *times* per *hour* The *sanatorium* is built high up among the mountains and forests in an absolutely isolated



Dr. Putzeys, General Secretary of the Eleventh International Congress of Hygiene and Demography.

spot which it takes two hours to reach by carriage from Spa. In the afternoon the members of the Congress were shown the sights at Spa and entertained at a banquet by the municipality. At the lunch at Borgoumont and at the dinner at Spa many congratulatory speeches were made and the members of the Congress were well pleased with all that they had seen.

There was also an excursion to the intake of the new water-supply for the suburbs of Brussels, when 60 members of the Congress went to Sovet The reservoirs, the galleries cut in the chalk, and the protective measures to prevent contamination of the gathering grounds were all examined Then there was a banquet at which Dr. PARMENTIER of the *Belgian Medical Gazette* in a speech rendered special homage to Dr. Voituron, the indefatigable secretary of the Congress, who had served as a connecting link between all concerned and had borne the brunt of the hard work. Dr. VOITURON replied that he was not alone but that the undoubted success which had been achieved was in a very large measure due to the great work done by the President, M. Beco, and the general secretary, Dr. Putzeys. These are opinions in which all who were present are likely to share. In conclusion, I think I may fully endorse the above remarks and further add that the Brussels Congress has been one of the best managed and most useful congresses of the entire series.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Visit to the Liverpool School of Tropical Medicine by the Right Hon. Joseph Chamberlain, M.P.

PRIOR to his departure from Liverpool at the close of his political engagements Mr. Chamberlain paid a visit to the School of Tropical Medicine, in which he took so deep an interest while at the head of the Colonial Office As is well known the existence of the Liverpool School of Tropical Medicine is primarily due to Mr. Chamberlain who was desirous that something of a practical nature should be done to make the West African colonies more healthy for white men. He was ably and enthusiastically backed up by Sir Alfred Jones, K.C.M.G., who has been the chairman of the school from its inception. Mr. Chamberlain being desirous of inspecting the school put himself into communication with Sir Alfred Jones who promptly made all the necessary arrangements for the visit. At the same time Sir Alfred Jones took steps to insure that, as far as possible, Mr. Chamberlain's desire that the visit should be of a private and informal character should be carried out. The research portion of the Tropical School work is situated at the University buildings in Brownlow Hill, while the clinical ward of the school is at the Royal Southern Hospital. Both institutions were therefore included in Mr. Chamberlain's tour of inspection. Mr. Chamberlain, accompanied by Mrs. Chamberlain and the Earl of Derby, arrived at the University before noon. The visitors were received by Vice-Chancellor A. W. W. Dale, Sir Alfred Jones, Professor R. W. Boyce, Professor C. S. Sherrington, Major Ronald Ross, C.B. (head of the Tropical School), Dr. A. S. F. Grünbaum, and several members of the committee of the Tropical School. The visitors were first conducted to the new Johnston laboratories where the research work of the Tropical School is carried on. Major Ross conducted Mr. Chamberlain and party over the school, explaining all the details of the work, and the right hon. gentleman displayed the keenest interest in everything shown to him. Amongst other things, Major Ross was fortunately able to show him a new parasite of man which has just been discovered in India and was sent by the discoverer to the Liverpool School of Tropical Medicine for investigation. Mr. Chamberlain was extremely interested in the new parasite and in the specimens of mosquitoes which Major Ross was able to show him. It was explained to Mr. Chamberlain that at the present moment there are many students at the school, several of whom have come from foreign countries. About an hour was spent in inspecting the school, after which the party were driven in Lord Derby's carriage to the Royal Southern Hospital in the tropical ward of which are 12 patients, chiefly suffering from malaria The visit to the Royal Southern Hospital also proved of much interest to Mr. Chamberlain and party.

Liverpool Royal Infirmary: Presentation to the Honorary Treasurer.

A pleasant little gathering took place in the board room of the Royal Infirmary on Nov. 4th, when the committee, the medical staff, and other friends of the institution presented the honorary treasurer (Mr. Ralph Brocklebank) with his portrait painted in oils by Mr. Hall Neale, a local artist, in recognition of his long services to the Royal Infirmary. Mr. James Lister, the President, made the presentation to Mr. Brocklebank in a felicitous speech. The picture bore the inscription: "Ralph Brocklebank, hon. treasurer of the Royal Infirmary since 1879, and chairman in 1898 and 1899. Presented by his friends and colleagues in recognition of his work and services in connexion with the hospital." Amongst the honorary medical officers present were Sir William M. Banks, Dr. A. Davidson, Dr. T. R. Glynn, Dr. R. Caton, Dr. A. Bernard, Mr. Rushton Parker, Mr. F. T. Paul, Dr. T. B. Grimsdale, Dr. T. R. Bradshaw, Dr. John H. Abram, and Mr. G. G. Hamilton.

University of Liverpool: Inaugural Ceremony at St. George's Hall.

A brilliant scene was witnessed at St. George's Hall on the afternoon of Nov. 7th on the occasion of the ceremonial inauguration of the University of Liverpool. The programme consisted of the formal presentation of the charter to the first Chancellor of the University (the Earl of Derby, K.G.) by the Lord Mayor (Mr. W. W. Rutherford, M.P.) in his capacity as chairman of the university committee, and congratulatory speeches by the mayors and deputy mayors of neighbouring towns and by Sir Oliver Lodge, the principal of the University of Birmingham, late professor of physics at University College, Liverpool. The large hall was filled to its utmost capacity with the *élite* of the city and neighbourhood and an element of hilarious enthusiasm was provided by large bands of students who occupied the galleries. The chief participators in the ceremony, wearing their distinctive robes, formed into procession, entered the hall punctually at 3 P.M., and ascended the platform in the following order: the registrar (Dr. Londini), graduates (ladies and gentlemen), professors and lecturers of the faculties of engineering, law, medicine, science, and arts; the court and council, mayors and civic dignitaries, the vice-chancellor (Principal Dale), the pro-chancellors (Mr. E. K. Muspratt and Sir Edward Lawrence), the Lord Mayor and Sir Charles Petrie (the ex-Lord Mayor), and the Chancellor (the Earl of Derby). The scene on the platform was strikingly picturesque, full of colour and pleasing contrast. The Chancellor, who occupied the chair, was attired in his Privy Council robes and the pro-chancellors and the vice-chancellor wore their official robes for the first time, those of the pro-chancellors being of black silk, richly ornamented with silver lace, with academic caps with silver bullion tassels, and those of the vice chancellor's also of black silk, faced with crimson velvet and white fur, worn under a deep ermine cape faced with crimson velvet and fastened with white silk frogs, tassels, and silk cords. The National Anthem having been sung to the organ accompaniment of Dr. Peace (the city organist), the Lord Mayor in a brief speech of congratulation handed the charter of incorporation to Lord Derby who suitably accepted it in a graceful speech. Expressions of congratulation on the success of the application for a university charter from various civic representatives followed. Sir Oliver Lodge, the principal of Birmingham University, also offered the congratulations of that body to the authorities of the new University. The vice-chancellor (Principal Dale) having acknowledged the various congratulations the proceedings terminated.

The Prevalence of Measles in Lancashire.

In his annual report to the Lancashire county council the medical officer of health (Mr. E. Sergeant) states that one of the most fatal of infectious diseases at the present time is measles and that this malady during the year 1902 gave rise to 653 deaths. Its prevalence is much increased by attendance at elementary schools. In populous localities these schools act as centres of rapid and extensive propagation of infectious diseases among the pupils. As a precautionary measure, therefore, not only children themselves suffering from measles but also members of the invaded households should be excluded from school until danger of their communicating the disease has passed. He adds that when means fail effectually to control the spread of measles the closure of the schools may with advantage be prescribed.

Nov. 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

New Hospital for Monmouth.

THE Monmouth dispensary was established so long ago as 1810 and in 1868 the institution was enlarged to accommodate nine in-patients. The inconvenient arrangement of this building and its inadequacy for the needs of the district have, however, for some time been apparent, so that it was a great relief to the managers when a few years ago Lord Llangattock very generously offered to assist in the provision of an entirely new building. An admirable site on which the old county gaol stood was secured and after the gaol was demolished a new hospital was erected, the institution being formally opened on Nov. 6th by Lord Llangattock. His lordship contributed £2000 towards the £8000 required for the building and furnishing and £1200 were given by Miss Philpott of Maida-vale, London. The hospital is in one block and with its half-timbered gables and balcony approached by a flight of steps resembles a Kentish homestead. There is accommodation for 20 patients in two six-bed wards and eight single-bed wards.

Butchers and Tuberculous Meat.

The agitation of the butchers of Glamorganshire and Monmouthshire[1] to secure from farmers and cattle dealers a guarantee that animals purchased are free from tuberculosis has at length borne fruit. Those butchers who are members of their trade associations are evidently determined to act together, and at the end of September passed a formal resolution to the effect that "on and after Monday, Nov. 2nd, 1903, no live-stock will be purchased by members of the allied association unless a warranty be given." A large stock sale was held at Llantwit Major on Nov. 2nd and the butchers inquired if any warranty would be given. As the reply was in the negative the buyers from Barry, Cardiff, Newport, and the Rhondda valleys refused to make any purchases. On the same day at a sale at Cardiff a warranty was given by the auctioneer in connexion with a scheme of insurance and at a sale held at Newport on Nov. 4th a guarantee was given by the farmers and dealers. It is stated that at both the Cardiff and Newport sales the prices realised were higher than at Llantwit Major. The principal argument used by the butchers in favour of securing a guarantee is that while they see the animal purchased for a few minutes only the farmer has opportunities of finding out its condition during many months. The farmers, on the other hand, declare that it would be impossible to put into actual practice any scheme of compensation owing to the difficulty there would be in identifying a particular carcass, to which the butchers reply that a distinguishing mark might quite easily be placed upon the hide. The most reasonable solution of the difficulty would appear to be in the adoption of some form of insurance with the premium paid jointly by the purchaser and vendor. During last year about 40 head of cattle were seized in Cardiff and about 15 in Newport and it has been estimated that a premium of 1*s.* on each beast sold would provide a sufficient insurance fund. It is satisfactory to find that the Cardiff butchers admit that the meat inspection as carried out at the public slaughter-houses is very rigid and that there is very little chance of diseased meat escaping the inspectors. It appears that it has for some years been the custom for the auctioneers to give to the butchers 1*s.* per head for cattle and 1*s.* for each pen of sheep purchased as "luck money," and the insurance scheme mentioned above as having been adopted at the Cardiff stock sale involved the retention by the auctioneer of this "luck money" on the understanding that he would himself give a guarantee with respect to the animals sold.

Refuse Disposal at Cardiff.

The question of providing a refuse destructor for Cardiff has been discussed by the corporation over and over again during the past 20 years and more than one definite recommendation has been made by the health committee. A special subcommittee recently reported at some length and advised the erection of an 8 cell destructor at an estimated cost of £15,000. The working expenses, it was considered, would amount to £2300 annually but there would be an annual saving of £500 in haulage. At present the Cardiff refuse is removed to tips on the outskirts of the town. In view of the heavy expenditure to which the corporation is already committed—noticeably in connexion with the new town hall and law courts—it has been decided to continue the present insanitary method of dealing with the town refuse. The corporation has decided to purchase two motor scavenging carts at a cost of £500 each.

Rainfall.

Although the rainfall during October was excessive in al parts of the country there was a remarkable difference between the amounts of rain which fell on the two sides of the Bristol channel. At Bristol and at Weston-super-Mare on the eastern side 7·7 and 8·3 inches were recorded respectively, while on the western side there fell at Newport 14·6 inches, at Cardiff 10·4 inches, at Swansea 11·4 inches, and at Carmarthen 15 8 inches. In the hilly districts of South Wales, as might be expected, there was a still greater increase. The rain gauge at the Cardiff collecting reservoirs in Breconshire recorded 21·4 inches for October and 101·3 inches for the ten months of the year; at the Swansea gathering grounds at Cray, where large reservoirs are now being constructed, 33 4 inches fell during October and no less than 182 8 inches have fallen during the present year; at the head of the Rhondda valley, which is 1700 feet above sea-level, 20 5 inches were recorded during October and 98 inches during the ten months of the year.

Vaccination Expenditure.

At the meeting of the Wellington (Somerset) board of guardians held on Nov. 5th it was reported that the cost of vaccination for the four years previous to the passing of the Vaccination Act was £210, while for the four years subsequent to the enforcement of the Act it was £636. The guardians decided to write to the Local Government Board expressing the opinion that that Board when calling for such returns as those of vaccinations, which involved so much additional work to the clerk, should pay for such extra services.—At the meeting of the Wells (Somerset) board of guardians held on Nov. 3rd it was reported that for the four years previous to the passing of the Vaccination Act the fees paid to the public vaccinator amounted to £124, while the fees for the four years subsequent to the passing of the Act were £395, an increase of £271, although fewer children were vaccinated during the latter period.—At the meeting of the Newton Abbot (Devon) board of guardians held on Nov. 4th it was reported that for the four years preceding the enforcement of the Vaccination Act the fees paid to public vaccinators amounted to £874, whilst for the four years following the passing of the Act the fees were £1202.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New Master of the Rotunda Hospital, Dublin.

A "CHARTER" meeting of the governors and guardians of the Rotunda Lying-in Hospital was held on Nov. 8th. The seventh and final year of office of Dr. R. D. Purefoy as master of the institution having expired the following motion was passed unanimously:—

[illegible] Hospital, on the retire-
[illegible] office of master of the
[illegible] to him for his devoted
[illegible] ffice and to the interests
[illegible] appreciation of the dis-
[illegible] we most warmly con-
[illegible] e hospital and on the
[illegible] been effected during his
[illegible] assisted to have carried
[illegible] our best wishes for his
success in his future career.

The ceremony of presentation to the hospital of a bronze bust of Dr. Purefoy by the past and present nurses of the institution took place on Nov. 3rd in connexion with the expiration of his term of office. The governors proceeded with the election of a new master, when Mr. Ernest Hastings Tweedy was declared duly elected master by a majority of votes.

---

[1] THE LANCET, August 8th, p. 428, and Sept. 12th, p. 793.

Mercer's Hospital, Dublin.

At the monthly meeting of the governors of Mercer's Hospital held on Nov. 3rd Dr. Seton S. Pringle was elected a visiting surgeon to the institution, vice Dr. Henry Croly.

The Typhoid Fever Problem in Belfast.

At a meeting of the City corporation held in Belfast on Nov. 2nd great dissatisfaction was expressed at the attitude of the public health committee in not discussing Dr. J. Lorrain Smith's report, but it appeared that a report presented to the public health committee by its executive sanitary officer, Mr. C. Scott, C.E., which was sent to each member of the council was to be regarded as a reply. In this report Mr. Scott considers the recommendations and remarks of Dr. Smith. In reference to the shell-fish he points out that there is no legal power to prevent the collecting or selling of shell-fish. As to milk, he says that new regulations came into force in reference to dairies, cowsheds, and milk-shops within the city on Sept. 4th, 1903. As to milk brought in from the country, he admits that there is no control, but adds that the number of cases of typhoid fever due to infected milk has been very small. In reference to pig-keeping there are, it seems, still about 2556 pigs kept in the city and Mr. Scott recommends that the distance from the pig-sty to the houses be increased from 15 to 50 feet. He recommends that all sewers should be constructed with a sufficient number of inspection chambers and ventilation shafts should be provided when the sewers are being constructed. Between January, 1899, and September, 1903, the number of houses in which the drains were reconstructed was 18,330. The average rate at which the house drains of the city are being reconstructed is about 2900 annually. Between April, 1899, and September, 1903, the drains of 11,869 houses were tested, of which 4103 were found to be defective; that is, 35 per cent. of all the drains tested were found to be defective. Further and more systematic testing of house drains should be done. Between Jan. 1st and Sept. 19th, 1903, it appears that 55,176 houses were inspected and 1463 written and 2312 verbal notices were given to the tenants to cleanse their habitations, and in this same time 6160 premises were cleansed. Finally, Mr. Scott deals in a very trenchant way with susceptibility to disease, with the wretched conditions under which the poor live, people who sleep with their windows closed, who avoid cold water as if it were a sin to use it, and who live chiefly on stewed tea and white (household) bread, the teapot rarely off the fire—tea for breakfast, for lunch, for dinner, and for supper—and, he argues, a population of this type will be liable to take every infectious disease on the whole list, especially tuberculosis and other kindred diseases, their resisting power being reduced to a minimum by foul air, filth, and unwholesome food. If the people in the towns could go back to the old-fashioned diet of porridge, milk, broth, and wholemeal bread their physique, their general health, and their disease-resisting power would be increased. Sanitary science, Mr. Scott thinks, has been too much occupied in producing so-called satisfactory statistics of births and deaths, forgetting that the true test of efficient sanitation is the production of a healthy, energetic, and disease-resisting people. A report was also received from one of the officials of the works committee pointing out the unsatisfactory state of many of the sewers of the older portions of the city. It is, in fact, perfectly clear from various sources that the drainage system of Belfast is in a deplorable condition and that in the past there has been most grave inefficiency of administration.

Ulster Medical Society.

The present session of this society was opened on Nov. 5th when the inaugural address was delivered by the President, Dr. John Campbell, surgeon to the Samaritan Hospital for Women, Belfast. Taking for his subject Some Minor Gynæcological Affections, he described at some length the various methods of treatment to be followed in cases of pruritus vulvæ, inflammations of the genital organs, lacerations of the perineum and the cervix, displacements of the uterus, pains for which there was no tangible cause, backache, and urethral caruncle. With respect to displacements he said that practically only backward displacements and descent need be considered. When the uterus was freely moveable replacement and the insertion of a pessary were the proper treatment but when there was fixation to even a slight degree the less the organ was meddled with the better. Prolapse of the uterus was not much benefited by repair of the perineum unless the repair were carried so far forward as almost to close the vagina. This was impracticable in most cases so that it was necessary to resort to pessaries or when they could not be tolerated to pneumatic pads and bandages.

The Treatment of Consumptives in Belfast.

The public health committee of the corporation of Belfast having been defeated in its scheme for providing day shelters for consumptives in one of the public walks in a walled-in garden proposes now to advertise for a ten-acre field and to erect shelters there. Mr. Robert Brown, the honorary secretary of the Ulster Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis writes to the Belfast papers strongly objecting to such a plan, on the ground that no place can be secured except at the end of one of the tram-lines, to reach which would cost each person fourpence. What good, he says, would a piece of bread (brought by the patient from his or her home) washed down with a glass of milk, to be provided, do? On wet days few would travel to the shelters; when the weather was dry a large number would come and how would the accommodation and the amount of milk be regulated, and would the public allow coughing consumptives to ride backwards and forwards in public vehicles? He advocates the erection of a proper sanatorium and not such a scheme as the public health committee suggests, which is mere nibbling at the outside of the question. He points out what bungalows have done, all that is needed being an old country house with an administrative block and some cheap shelters. A month at such a place for each patient would teach him the value of fresh air and the importance of dealing properly with the expectoration. Such a place with 100 beds would give 1200 patients four weeks' treatment each year. This would probably be enough for Belfast if such a place as the old Royal Hospital were taken for all incurable cases, in which the infection is most virulent, both in and out of the workhouse. In Italy this fact is recognised and such cases are compelled to go to hospital, and as a consequence Italy, in spite of poverty and dirt, is freer from this disease than any country in Europe. The proposed addition of 20 beds to the Forster Green Hospital is good, as far as it goes, but is utterly inadequate. The cheapest way in the end, as pointed out by Mr. Brown, is to put forth every effort at once to crush out the fell scourge of consumption, and he thinks that 100 beds in a sanatorium, with a place to isolate incurable cases, would go far in five years to show in Belfast a distinct decline in a disease the prevalence of which is such a discredit to a modern up-to-date city.

Salaries of Union Medical Officers in Ireland.

A rather important conference was held on Oct. 31st in the board room of the Ballinasloe Union to consider the salary to be attached to the medical officership of the Filconnel district, for while the guardians propose £150 per year the Irish Medical association—backed as it is by THE LANCET and the British Medical Association—asks £200. After a long discussion Mr. Byrne, as one of the representatives of the ratepayers, proposed a motion requesting the Irish Members of Parliament to obtain the repeal or amendment of Clause 6 of the Irish Local Government Act, which precludes boards of guardians from obtaining—as formerly—half of any increase of the salaries of medical officers. The motion was carried and Mr. Byrne then proposed:—

> That we, the board of guardians of the Ballinasloe Union, do ask the various boards of guardians in Ireland and the Irish Medical Association to appoint deputations to meet at the Mansion House, Dublin, for the purpose of discussing the much vexed question of the dispensary doctors' salaries, and we suggest that the Local Government Board should appoint a member of their body, or one of their inspectors, to attend the meeting. Copies of this resolution to be sent to the various boards of guardians, Members of Parliament, and the Chief Secretary. The meeting to take place on Tuesday, the 1st December. Three members of each board to be appointed on each deputation.

The motion was adopted unanimously. Mr. T. T. Collins, on behalf of the medical gentlemen, proposed a vote of thanks to the guardians for the very cordial way in which they had met them. Mr. T. J. Rossiter seconded the motion which was carried and the conference came to a close.

Irish University Education.

According to the *Irish Times*, at the meeting of the Cabinet last week Mr. Wyndham's new scheme was not passed owing to most decided opposition. Legislation for the labourers has been promised and this will, so far as

Ireland is concerned, be her share of next session's measures. The recent Land Act involves a very large expenditure of State-guaranteed money for many years to come and any attempt to saddle the Exchequer with more obligations is deemed impolitic as far as Ireland is concerned. It is also rumoured that the Government whips had evidence of the greatest opposition to rendering university education in Ireland sectarian.

(FROM OUR OWN CORRESPONDENT.)

Naval Surgeons and Professional Secrecy.

A CONFLICT has recently taken place between the naval surgeons and the authorities of the naval engineering works at Indret. It is part of the duties of naval surgeons to look after the wives and children of workmen in the arsenals and naval engineering works and to send in a daily report of their visits. The question arose whether it was fitting for the surgeons to indicate in their reports the nature of the illness or whether they should mention some and keep the others secret. During the absence on leave of the principal medical officer the chief of the Indret works, M. Clauzet, ordered a first-class surgeon, Dr. Averous, to specify in his reports the nature of the illnesses from which the wives and children of the workmen were suffering and if the complaint came under the heading of a professional secret he was to notify this fact on his report sheets. Dr. Averous refused, saying that there was no list of diseases coming under the head of professional secrecy. Moreover, to name certain diseases and to conceal the nature of others would identify the case. M. Clauzet did not consider these reasons sufficient and put Dr. Averous under arrest. When the principal medical officer, M. Alix, returned he was informed of the situation and quite agreed with the view taken by his colleague. Dr. Averous has appealed to the authorities (*réclama par voie hiérarchique*) against his sentence and the matter has been submitted to the Naval Minister.

Sleeping Sickness.

In my letter which appeared in THE LANCET of Oct. 31st I drew attention to the discussion at the Academy of Medicine of this remarkable disease. At the meeting of the academy held on Oct. 27th M. Blanchard reminded the meeting that he had announced that M. Brumpt had been enabled to inoculate a monkey with the parasite of sleeping sickness, which monkey died after about six weeks, having previously presented all the symptoms of sleeping sickness. Film preparations made from the blood of this monkey and stained by Nocard's method showed numbers of the trypanosoma Ugandense. The monkey in question was a macacus cynomologus, an Asiatic species which had been purchased in Antwerp and sent to the Congo. Before any experiments were made, and also after inoculation, its blood was tested for parasites and none was found up to the thirteenth day after inoculation. The parasite only appeared later. This experiment is the first in which sleeping sickness in the monkey has [illegible] the previous [illegible] shown that [illegible] glossina pal[illegible] which were [illegible] to confirm those previously announced by Brumpt about June 27th concerning the intervention of glossina in a parallel case. Bruce, however, had only been able to show that he had found trypanosomata of an undetermined species in the blood of a monkey which had been bitten by some 200 glossinæ collected in the neighbourhood and consequently being possibly infected with trypanosomata of unknown origin. Moreover, the monkey showed parasites in its blood as early as the fourteenth day, while in two experiments made by Bruce, in which he inoculated a monkey successfully with cerebro-spinal fluid taken from a patient suffering from sleeping sickness, the parasites did not appear in the blood until the twenty-second or twenty-third day. It is probable, then, thinks M. Blanchard, that Bruce in the experiment with the monkey and the glossinæ inoculated a parasite of rapid evolution such as that of nagana and not that of true sleeping sickness.[1]

Congress of School Hygiene.

The Congress of School Hygiene and of the Physiology of School Mastering (*pédagogie physiologique*), which has been organised by sundry medical men and laymen for the improvement of [illegible] at Paris on Nov. 1st in the School [illegible] sat for two days. Papers were re[illegible]ld, amongst others, on the following subjects: the Duties of Medical School Officers; the Comparative Value of Morning and Afternoon Work; the Afternoon Rest; and the Division of Hours of School Work.

Infantile Gastro-enteritis treated by Starchy Foods.

At the meeting of the Pediatric Society held on Oct. 20th M. Méry read a paper in which he advocated the use of starchy food as a transition diet in the gastro-enteritis of infants. For the arrest of gastro-enteritis which depends upon intestinal fermentation there is nothing like plain water, but this diet cannot be continued for long. A return to a milk diet is often followed by a return of the diarrhœa and the child very often becomes more and more cachectic and finally dies. M. Méry has obtained good results by giving starchy foods after stopping the plain water and before going back to milk. He uses starch water, rice water, and vegetable soup. This last, together with rice water, has given very good results, superior to those obtained with modified milk, skim milk, or butter. In infants who are more than six months old the results have been admirable; in those under that age they have not been so good. But in all cases the weight of the infants has increased, even in those who died. This feature is not due to the food value of starch but is due to retention of water by the tissues. The proportion of salt in a vegetable decoction is double that of milk and it is reasonable to suppose that an organism overcharged with salts will fix a certain quantity of water. Some children, in fact, exhibit œdema without albuminuria. This œdema disappears when they are put upon a milk diet but they also lose weight. It is easy, then, to see how a vegetable diet can successfully prevent the rapid dehydration which occurs in children suffering from gastro-enteritis.

Appendicitis in the Army.

At the meeting of the Academy of Medicine held on Nov. 3rd M. Chauvel, formerly the head of the Naval and Military Sanitary Department in Paris, read a note upon the above subject. M. Chauvel has published a former report upon this subject, but that one dealt with certain uncommon and very serious cases which showed an enormous mortality —viz., 31·8 per cent. In the present paper M. Chauvel gave a general view of military appendicitis and by official statistics which he brought with him showed that the mortality was only 14·9 per cent., a figure which compares well with those obtained in civil hospitals. One very remarkable point is the extreme rarity of appendicitis in Algeria, at least among the natives. Excess in food is very rare among them and so also is influenza. M. Chauvel's paper brought up M. Lucas Championnière to answer and in his reply he said that every day more and more confirmation was forthcoming of the idea that it was the abuse of a meat diet which was the principal cause of appendicitis. In those countries where the natives eat very little meat, as in Brittany, appendicitis is very rare. In England and the United States, where a great deal of meat is eaten, appendicitis is four times more common than in Paris. As to the rôle played by influenza there is at present an inquiry being carried out in the usual manner in Tunisia and on the coasts of Italy, where the first epidemic of influenza in 1889 was particularly severe. The object of this inquiry is to find out if in those countries which are very sparing from the point of view of a meat diet there was together with the influenza an outbreak of cases of appendicitis.

ROME.

(FROM OUR OWN CORRESPONDENT.)

An Italian Sanatorium.

THE ambitious scheme for providing sanatoriums for the *open-air treatment of pulmonary consumption*, which was drawn up by an influential committee under the presidency of Professor Baccelli shortly after the death of King Humbert three years ago, has so far gone little beyond the subscription stage, and it has been left to private effort to establish the first institution of this kind in Italy on any large scale. The "Primo Sanatorio Italiano," which is now open to receive patients, was begun two years ago with a capital of about 500,000 lire (£20,000), raised by private enterprise on the initiative of Dr. A. Zubiana, under whose direction the building was erected and to whose care the management of the establishment has been entrusted. Situated at Sondalo in the midst of the large pine forest of Sortenna in the Valtellina and at a height of 1250 metres (4100 feet) above sea level, and favoured by the sunshine and warmth of an Italian climate and a purity of the atmosphere not inferior to that of the neighbouring Engadine, the new sanatorium enjoys great natural advantages. It is well sheltered from the winds by a background of high mountains and by the forest of larch and pinewood around it, while it commands magnificent views of the lovely valley beneath. Far from any human habitation, it is reached in about three hours by a carriage road from the station of Tirano on the Colico-Sondrio railway and is therefore within an eight hours' journey by rail and road from Milan. The sanatorium has 60 beds and all the bedrooms have a southern aspect, most of these being also provided with balconies. It is constructed and furnished in the most approved and up-to-date manner, the angles at the floor and ceiling of the bedrooms and corridors being all rounded, the walls covered with washable glazed linen or painted and varnished, and the floors laid with tiles, linoleum, or wooden parquets. There are electric light and steam heating at low pressure throughout and ventilation is secured in all the rooms by windows furnished above and below with double casements. An excellent water-supply, which is brought from sources at Escio, nearly a mile off, is distributed through all the rooms and corridors and there is abundance of hot water on every floor. There is a plunge bath for every eight rooms and a complete installation for hydrotherapy, massage, and inhalations has been provided. Annexed to the waiting-room are rooms for laryngoscopy and radiography and a chemical and a bacteriological laboratory. There is also an operating room for cases requiring operative interference. The laundry is worked by steam and is supplied with apparatus for sterilising clothing and spittoons. The verandahs, which are so placed as to command the lovely view, are large and airy and provided with chairs made to revolve. Besides a large and lofty dining hall there are six public rooms, including drawing, reading, writing, recreation, music, and ladies' drawing rooms. There are covered galleries for bad weather, while in fine weather the patients can enjoy walks of the most varied kind through the avenues and footpaths in the garden and the surrounding woods. Owing to the slope of the site on which the sanatorium is built it has been possible to provide each floor with a bridge over which patients can pass on the level in order to gain access to the grounds.

Cases of Supposed Poisoning in a Hospice.

During the first week of October there died at the Hospital of San Giovanni two children who had been conveyed thither from the Hospice of Santa Margherita, a reformatory and orphanage in Rome containing about 200 inmates. The cause of death was proved by a necropsy to be enteric fever. Two of the nursing sisters, a teacher, and several other children at the institution had sickened at about the same time, the severer cases being likewise removed to the Hospital of San Giovanni and all presenting symptoms of typhoid fever. On the 14th and two succeeding days about 20 other children at the hospice became suddenly ill but with different symptoms, there being no fever but very grave signs of gastro-intestinal irritation of an almost choleraic character. The worst of these cases were also removed to the hospital, where on the 18th two of them died after 18 hours of suffering, with vomiting, agonising pains in the abdomen, frequent bloody stools, cyanosis, and collapse. The whole hospice was meanwhile cleared out and thoroughly disinfected. In carrying this out it was found that the sanitary arrangements were very defective, the sewers for one thing never having been connected with the main sewers of the city. That there was no question of typhoid fever infection in the last group of cases was, however, conclusively proved by the necropsy of the two fatal cases which showed that death was due in each of them to poisoning from the ingestion of some powerful irritant. There were acute and diffused peritonitis, large necrotic erosions of the stomach, acute enteritis, and acute nephritis—such lesions, in short, as might have been caused by a strong caustic such as corrosive sublimate. An analysis of the viscera and their contents is being made; meanwhile it is believed that through some lamentable blunder on the part of the attendants powders containing perchloride, in place of subchloride, of mercury must have been administered to the children as a purgative. A third death with similar symptoms and post-mortem appearances has since taken place and one more at least of the unfortunate little patients will probably succumb before the toll of victims is complete.

Proposed International Congress on Malaria at Rome.

The following motion was proposed by Professor Queirolo of Pisa at the Congress of Internal Medicine, lately held at Padua, and carried by acclamation:—

> Considering that Italy, chiefly through the merit of the Roman school which has promoted and cultivated with such zeal and signal success the study of malaria, holds the first place in respect of these researches; also in view of the fact that the victories achieved by science in this field have led to [illegible] the prophylaxis of malaria, this [illegible] the promotion of an internationa[illegible] be held in Rome.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Cancroin of Professor Adamkiewicz.

SOME years ago Professor Albert Adamkiewicz of Cracow in Austrian Poland read a paper in Vienna announcing the discovery of a remedy against carcinoma. This remedy, to which he gave the name of cancroin, was a solution of choline, citric acid, and phenol. The most eminent physicians and surgeons, however, such as Billroth, Albert, and Kaposi, agreed that this method of treatment had nothing to recommend it and Professor Adamkiewicz has therefore sought some other way of inducing the profession to make use of cancroin. In the middle of October the chief surgeons of the public hospitals belonging to the State were surprised by receiving an order from the Home Secretary to make trials of the cancroin of Professor Adamkiewicz. This remarkable and unprecedented order has naturally aroused much indignation in medical circles. Professor Adamkiewicz also called the newspapers to his aid, publishing most encouraging results of the treatment of cancer by means of cancroin, but Dr. Husche of Rostock has stated that one of the patients whom Professor Adamkiewicz and Dr. Katscher claimed to have cured really died from cancer of the stomach a short time after treatment with cancroin.

"Grande Crise Gastrique."

A paper on this subject has been read by Professor Pal before the Vienna Gesellschaft der Aerzte. He found that there was a very great increase of vascular tension during the gastric crisis, often to the extent of 150 per cent. of the tension under normal conditions in the same patient, but this increased tension was by no means produced through pain, as some investigators have supposed, because very violent attacks of pain, according to Professor Pal, produce only depression of the blood pressure. Professor Pal found that the blood pressure increased before the pain began and that the vascular tension, in fact, caused the pain. The high vascular tension disappeared at the same moment as the pain did. Through artificial depression of the vascular tension it was possible to control the pain and all the other symptoms of the "crise gastrique." If the depression of the vascular tension comes to an end the pains are renewed. The effect of morphia presents points of interest, for morphia only soothes the pain through blunting the sensibility and the peculiar symptoms of the crisis may remain. Professor Pal explains the "grande crise gastrique" as being a vascular phenomenon, a peculiar contraction of the smallest vessels of the intestines. All conditions found during the crisis were directly or indirectly produced by this fundamental phenomenon—namely, the irritation of the vasoconstrictor branches of the splanchnic nerves. In the discussion Professor Winternitz remarked that very often the attacks of pain in tabes dorsalis were not associated with an increase of blood pressure, but, on the contrary, with depression of it. Professor Winternitz had also seen some cases of gastric crisis with high tension of the blood-vessels, but in another case it was possible to observe in the normal state high blood pressure and during the attack of "crise gastrique" a very low one.

Reflex Palsy of the Extremities and Reflex Impairment of the Power of Writing and Speaking.

A paper on this subject has been read by Professor Urbantschitsch before the Gesellschaft der Aerzte. He said that in cases of otitis media palsy of the extremities occurred sometimes, but medical men did not recognise a connexion between this symptom and otitis media although it was not difficult to show that the treatment of otitis when successful was followed also by a diminution of the palsy Impairment of the power of writing was often produced by otitis media, by pressure on the mucosa of the middle ear, and by syringing the ears The introducing of tampons into the ear might in about one fifth of the cases act similarly The same causes produced reflex paresis of the muscles of vocalisation with consequent impairment of speech Many patients who were suffering from ear disease spoke with difficulty and only in a slow hesitating manner; some letters, especially "s," they were quite unable to pronounce Often they were unable to read fluently Professor Urbantschitsch had observed patients suffering from ear disease and presenting symptoms similar to apoplexy in whom the treatment of the ear complaint showed the reflex nature of this paresis beyond a doubt Similar symptoms of paresis were also produced by irritation of the sensory nerves of the mucous membranes of the nose and mouth, but after cocainisation of the mucous membranes of the ear, nose, and mouth it was impossible to elicit the same effect, a sign of the reflex nature of this peculiar disease It seemed to be necessary to examine the ear and nose in all cases of paresis of the extremities and impairment of the power of speaking and writing

Experiments on Living Animals

The anti Semitic Landtag (Diet) of Lower Austria has prohibited vivisection and all experiments on animals in the hospitals under its control As the obstetrical clinics of Vienna University receive financial support from the Landtag and are under its control this assembly has ordered all experiments of every kind on animals to be stopped The professors of obstetrics protested against this order but as yet without any results The same Landtag sanctioned a grant to the university polyclinic only under the condition that Jewish professors should be subject to the authority of Christian professors in their treatment and prescriptions

NEW YORK

(FROM OUR OWN CORRESPONDENTS)

The Sale of Headache Remedies in New York

THE facility with which persons can obtain powerful and dangerous drugs in the druggists' shops of New York city has been recently engaging the attention of writers on medical matters This is especially the case with regard to headache remedies These are sold in enormous quantities to individuals who are entirely ignorant either of the action of the powerful drugs therein contained or of the cause of the pain from which they desire to obtain relief The druggist assures the sufferers that certain powders, wafers, or tablets will have the desired effect and, indeed, in a very large number of instances temporary relief is quickly obtained The druggist will also declare that the remedy advocated is harmless The majority of these remedies are mainly composed of acetanilide phenacetin, antipyrin, or of some other of the coal tar derivatives and are consequently, when not absolutely dangerous, in a high degree depressing The medical journals of New York have been warning the public for some time against the indiscriminate use of the drugs known as headache remedies

Dowie in New York

The descent upon New York of Dowie and his restoration host from Zion City has been made the theme of discussion by some of the medical journals and by all the lay journals The *New York Medical News* treats the question from a psychological standpoint and seems to maintain that the so called Dr Dowie is more or less insane The writer of the article is of the opinion that he is the victim of a conviction of reincarnation such as is so common among the insane that every asylum in the country has some examples of it "Further," the writer says, "with this fixed idea become a ruling passion there is combined a capacity for business and the administration of affairs, a positive genius for organisation, and withal a persuasiveness of language and a magnetism of personality that make the possessor of these heterogeneous qualities a most interesting subject for study and painstaking investigation " The majority of the journals take a far more material view of the matter and insist that Dowie is simply a clever fakir who, knowing human nature, plays upon the weaknesses of mankind in order to make money and at the same time to gratify his vanity Whether Dowie, Mrs Eddy, and others of the same kind are influenced by good motives or not one thing at least is certain that they cause a great deal of harm and for this reason alone should be suppressed To the ordinary observer it would seem that they fleece their followers and those of the outside public who allow themselves to be deluded in order to live in luxury invested with a notoriety which they are persuaded is fame Perhaps the most unpleasant feature of Dowie's miscalled religious tenets is his professed belief in faith cure If grown up persons refuse to be treated by a medical man when injured or when attacked by disease no valid objection can be made to their action, but when a parent or guardian will not allow a sick child to be treated by a qualified physician or surgeon then it is perfectly right that such an individual should be severely punished Even in the United States, where every latitude is allowed to the irregular fraternity, this view of the case is beginning to impress itself upon the minds of the community at large

Yellow Fever Quarantine in Texas and Louisiana

It was announced on Oct. 23rd that the Governor of Texas had quarantined the whole of that State against San Antonio where yellow fever is prevalent Railroads are forbidden to operate trains in or out of San Antonio or to handle any freight or passenger business from that city until the quarantine is removed On Oct 23rd the Louisiana State Board of Health issued a proclamation of quarantine against Laredo and San Antonio, Texas and in addition to this all railroads and other common carriers were prohibited under penalty from bringing into Louisiana passengers, household goods, and cars from those places unless they were first fumigated with sulphur by authorised health authorities The situation as regards yellow fever is declared to be encouraging at San Antonio and much indignation has been expressed at the action of the Governor of Texas in proclaiming a State quarantine against that town, while no such step has been taken with regard to Laredo where the disease is said to be more widespread

Nov 3rd

Obituary.

PHILIP BROOKES MASON, M R C S ENG , L S A.,

CONSULTING SURGEON TO THE BURTON ON TRENT INFIRMARY

THE profession is the poorer by the death of Philip Brookes Mason, a man of sterling qualities and excellen intellectual gifts, as the following record of his academical career will show Mason commenced his medical education in 1858 by spending a winter and a summer session in Glasgow, where he gained prizes in the classes of anatomy, chemistry, and botany After that he spent a year in his father's surgery at Burton on Trent and then entered at University College, London, where he gained seven gold and silver medals as well as the Filliter exhibition of £30 in pathological anatomy, the Longridge exhibition of £40 for general proficiency in medicine and surgery, and the Atkinson Morley scholarship of £45 a year for three years in surgery In 1864 he became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries He was house surgeon in the hospital to Mr Erichsen and Sir Henry Thompson In 1864 he was appointed demonstrator of anatomy in University College and held that appointment for three years, and in this position in the temporary absence of Professor G V Ellis, delivered the lectures in the class of anatomy In the University of London he obtained at the preliminary examination (scientific) exhibitions of £40 a year for two years in biology and also in chemistry and materia medica In 1866 when he was intending to present himself for the second M B examination in the University of London and the final examination for the Fellowship of the Royal College of Surgeons of England, cholera broke out in London and he was appointed by Dr George Buchanan, whose work as assistant physician at the Hospital for Sick Children in Great Ormond street he had been doing during that summer, to the charge of the temporary Hospital for

Children for the parishes of St. Giles and Bloomsbury. Early in 1867 his father died suddenly, leaving his family unprovided for, and he was obliged to take over his practice, and the duties of a very large country practice effectually put a stop to his passing any more examinations and thus it was that he never held the higher degrees. From 1870 he was surgeon to the Burton-on-Trent Infirmary, which now contains 60 beds and serves a large manufacturing, railway, and colliery district, and this afforded him considerable practice both in general and in operative surgery. He was the first surgeon in the neighbourhood to perform ovariotomy and that successfully. He was also surgeon to the Burton-on-Trent Dispensary and to the Post Office.

With regard to his private life a friend writes: "He never took any part in municipal politics. I believe he never voted in a municipal election of any kind and never more than once, I believe, in a Parliamentary one. He was elected a member of the Burton Feoffees for the administration of the combined charities in 1882 and was chairman of that body in 1898. In 1888 he was made a magistrate of the borough of Burton-on-Trent, being one of the gentlemen appointed when the borough bench was first formed in that year. He continued to sit on the bench up to 1899. He was from its foundation a member of the Burton-on-Trent Archæological and Natural History Society and was at one time president. He read several important papers before the society."

Mr. Mason was a great naturalist and made many communications to the Linnæan and cognate societies. He was a born collector and once said that he began collecting at the age of four years. No natural curiosity came amiss, but it was to insects, and especially beetles, that he was mainly devoted. His specimens were mounted (by himself) with the greatest neatness and skill and some years ago had assumed such proportions as to lead him to build a fire-proof museum adjoining his house, and here it was that he spent almost every moment of his leisure. This collection is a wonderful one to have been brought together by one man. The specimens in it must amount to many thousands and their arrangement is most skilful. He had probably the largest collection extant of British beetles, but of the scientific value of the collection it must be left to entomologists to speak. Mr. Mason married rather late in life Miss Saunders, the daughter of Mr. William Saunders, a Burton brewer. This lady proved a most suitable helpmate and during his somewhat prolonged illness nursed him with the most unremitting and tender care. But for his father's sudden death Mr. Mason must have taken a high position in the scientific and medical world and would doubtless have joined the teaching staff of a medical school. His death will be greatly lamented by University College men whose memories take them back to the "sixties." Among his fellow students were Sir John Williams, Sir R. Douglas Powell, Matthew Berkeley Hill, H. C. Bastian, Sir W. R. Gowers, Marcus Beck, G. V. Poore, F. T. Roberts, John Tweedy, and others who have become known to the profession.

He died on Nov. 6th and was buried at Burton on the 9th, a large number of sorrowing friends being present at the funeral. He left no issue.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Friedrich Betz of Heilbronn, at the age of 84 years. In early life he was a prolific writer on medical subjects and was the first editor of *Memorabilien*. —Dr. Fochier, professor of midwifery in Lyons.—Dr. A. Gallet, professor *agrégé* of surgery in the University of Brussels and surgeon to the St. Jean Hospital in that city. —Dr. Brassac, formerly director of the Medical Department of the French Army.

MEDICAL MEN AND THE MUNICIPAL ELECTIONS.—At the meeting of the Monmouthshire County Council held on Nov. 4th Mr. John Davies James, M.R.C.S. Eng., L.S.A., was elected an alderman.—At Newport (Mon.) municipal election Mr. Sutton, L.R.C.P., L.R.C.S. Edin., was returned for the St. Woolos Ward.—At Bristol on Nov. 2nd Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., was returned for the Horfield Ward by a very large majority.—Dr. Henry Dutch has been returned councillor for the Grosvenor Ward, City of Westminster Council.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in Anatomy and Physiology:—

Charles Ernest Anderson, King's Colleg [illegible] son Billings, London Hospital; [illegible] ohn Butterworth, L.D.S. Eng., Owens [illegible] uel Earle Cathcart, Middlesex Hospital; [illegible] University College, Cardiff; Samuel Wilfrid Daw, Guy's Hospital; John McDougall Eckstein, St. Bartholomew's Hospital; Harry Rumsey Edwards, King's College Hospital; Albert Edward Evans, University College Hospital; Shiavax Hormuzshaw Gandhi, Bombay and Owens College, Manchester; Percy Charles Garrett, Owens College, Manchester; Frederic William Wandby Griffin, B.A. Camb., and Richard Athelstane Parker Hill, B.A. Camb., Cambridge and St. Bartholomew's Hospital; Elliott Thornton Glenny, Rupert Lawrence Haines, and William John Jago, St. Bartholomew's Hospital; Roderick Jackson, University College, Liverpool; Robert Bruce Low, University College Hospital; Peter Donald Fraser Magowan, Guy's Hospital; Joseph Leopold Meynell, London Hospital; Percy Moxey, University College, Bristol; Harry Williams Nicholls and Sidney John Rowneree, Middlesex Hospital; Alexander Morton Pollard, King's College Hospital; John Pugh, St. Mary's Hospital; George Andrew Russell, Birmingham University; Harold Kenneth Salisbury, University College, Bristol; Ernest Albert Saunders, King's College Hospital; Edgar Arthur Shirvell, London Hospital; George Alan Simmons, St. Thomas's Hospital; Herbert McLean Staley, Owens College, Manchester; John Tate and Arthur Christopher Watkin, University College Hospital; Christopher Tylor, B.A. Camb., Henry Cecil Waldo, Ambrose Cyril Wilson, and William Harrison Woodburn, B.A. Camb., St. Bartholomew's Hospital; and Ismael Valerio and Ernest Wragg, B.A. Camb., Guy's Hospital.

UNIVERSITY OF OXFORD.—The following dates are announced for the medical and preliminary examinations (in each case the date mentioned is that on which the examination begins):—Preliminary examinations in Physics and Chemistry, Dec. 7th, and in Botany, Dec. 14th; further examination in Mathematics, Dec. 14th (names to be sent in by Dec. 2nd); First M.B. examination (Anatomy, Physiology, Materia Medica, and Organic Chemistry), Dec. 9th (names to be sent in by Nov. 25th); Second M.B examination, Dec. 9th (names to be sent in by Nov. 25th); Preventive Medicine, Nov. 24th. The examination in Pathology in the second M.B. may be taken separately at any time after passing the first M.B. examination and before the remainder of the second M.B examination. Forms of entry, certificate forms, &c., can be had on application to the secretary to the Boards of Faculties, Clarendon Building, Oxford. Names entered late are admitted up to certain dates, which vary for the different examinations, on payment of an additional fee of two guineas. Degree days for this term are on Nov. 19th, Dec. 10th, and Dec. 17th.

LEEDS HOSPITAL FOR WOMEN AND CHILDREN.—The jubilee year of this hospital has been opportunely celebrated by the formal opening of an entirely new group of hospital buildings. The old building, which was not originally constructed for a hospital, will for the present be adapted as a residence for nurses and servants. The opening ceremony was performed by the Right Honourable the Viscountess Mountgarret on Oct. 30th. The new buildings will accommodate about 45 gynæcological patients and a few cots are provided in a separate ward for children In addition to these an isolated portion of the building has been specially arranged as a small lying-in hospital with space for five beds. This it is hoped will be the nucleus of a larger lying-in hospital when sufficient funds are forthcoming. Hitherto there has been no lying-in hospital in Leeds. The wards for the reception of gynæcological patients occupy a long two-storyed pavilion. The space under the ground floor is, owing to the fall of the ground, very extensive, and having been left unoccupied it allows of a free circulation of air beneath the entire pavilion. The wards are 100 feet long, 24 feet wide, and 13 feet high. Each bed has a linear space of 10 feet, a floor space of 120 square feet, and a cubic air space of 1560 cubic feet. All the windows are double, in order to counteract the cooling effect of the extensive window surface.

CENTRAL MIDWIVES BOARD.—At the last meeting of the Central Midwives Board a letter was read informing the board that a person representing himself as deputed by the county councils to receive the names and fees of midwives desiring to be certificated by the Central

Midwives Board had visited a nursing institution and had endeavoured to collect the fees The board consequently desires it to be known that the secretary alone is authorised to receive the fees and as it is in possession of a description of the impostor it trusts that the publicity of the press may lead to his early detection At the same meeting the secretary was instructed to add the Rural Midwives Association 47, Victoria street, London, S W, to the list of bodies to whom applicants for training in midwifery should be referred while the board resolved to receive the certificates of the following bodies as approved qualifications under Section 2 of the Midwives Act, 1902 (1) Queen Charlotte's Lying in Hospital (2) Manchester Southern and Maternity Hospital (3) Liverpool Ladies' Charity and Lying in Hospital, (4) British Lying in Hospital, (5) Glasgow Maternity Hospital, and (6) St Mary s Hospital, Manchester The names of 126 women were passed under Section 2 of the Act and ordered for entry on the roll Of this total 74 claimed as holding the certificate of the Obstetrical Society of London, three that of the Rotunda Hospital, Dublin, and 49 were admitted as having been in *bona fide* practice for one year prior to July 31st, 1902

UNIVERSITY OF CAMBRIDGE —As was expected in the University the electors to the chair of Physiology have appointed Dr J N Langley F R S, to be professor in succession to Sir M Foster, K C B The general board of studies has appointed Dr A. Hill to be University Lecturer in Advanced Anatomy, and Dr A. C Ingle to be University Lecturer in Midwifery The Allen scholarship, value £250 for one year, for research in medicine or other branch of science, is about to be vacant Graduates of the University under the age of 28 years may apply to the Vice Chancellor before Feb 1st 1904 stating the nature of the investigation they desire to pursue During the present year 88 candidates have been admitted to the examination in State medicine for the Diploma in Public Health 41 passed both parts of the examination The council of the Senate proposes that a syndicate shall be appointed ' to consider what changes, if any, are desirable in the studies, teaching and examinations of the University, ' to confer with such persons or bodies as it may think fit, and to report before the end of the Easter term 1904 The scientific members of the syndicate as proposed are Dr D MacAlister, Dr A. R Forsyth, F R.S, Professor J J Thomson F R S, and Mr W Bateson, F R S

THE FINANCIAL POSITION OF GUY'S HOSPITAL —At the annual general court of the governors of this hospital held on Nov 6th Mr H Cosmo Bonsor, the treasurer took the chair and made a statement with respect to the financial condition of the hospital He said that all the wards are now opened and more than 600 beds available for patients and that the cost of maintenance could not be less than £60 000 per annum Towards this the hospital had an income more or less assured of about £35 000 per annum and in addition had recently been in receipt of about £11,000 annually from King Edward s Hospital Fund for London, the Hospital Saturday and Sunday Funds subscribers and other sources leaving a deficiency in ordinary income of about £14 000 per annum The treasurer further reported that of the £180 000 appealed for in 1901 for renovation and building only £103,000 had been so far received and that the institution was in debt for the balance which had been made up by temporary loans It was unanimously resolved that, "The treasurer be requested to obtain the widest currency possible for a short statement of the present circumstances of the charity, and further to continue a vigorous appeal with a view of enlarging the basis of public support adequately to the increased needs of the establishment' Guy's Hospital has been rightly held up as an example to be followed by other metropolitan hospitals for its admirable internal arrangements and good and economical working and we feel very strongly that the charity ought to be relieved from the financial strain indicated by an annual deficit of £14 000 A hospital cannot any more than a private individual for ever live on its capital That Guy's Hospital is appreciated by the great British public has been proved by its position and by the number of beds constantly occupied To treat effectually 130 000 patients every year is no small task and a hospital which can carry on such a work with good results and economy deserves—nay, has the right to claim—support from the public Certainly Guy's Hospital has received some large special donations and legacies but the pressing needs of the hour have exhausted such sources of income as fast as they occurred We trust that the public will come to the rescue

A FEMALE VACCINATION OFFICER —At the meeting of the Chipping Sodbury (Gloucestershire) board of guardians held on Nov 4th a lady was appointed vaccination officer

HARVEST FESTIVAL —An interesting harvest festival was held in the chapel of the Cancer Hospital, Fulham road, London S W, on Nov 5th, at 7 P M, when a touching and appropriate sermon was preached by the Archdeacon of London The chapel was very prettily decorated, the work having been carried out by some lady friends of the hospital assisted by the matron and her sisters and nurses

GLASGOW OPHTHALMIC INSTITUTION POST-GRADUATE DEMONSTRATIONS ON DISEASES AND INJURIES OF THE EYE —The seventh annual course of demonstrations was inaugurated on Nov 3rd Dr R Perry, one of the managers of the Glasgow Royal Infirmary presiding Dr A Maitland Ramsay chose as his subject ' A Blow on the Eye its Immediate and Remote Results ' The attendance was larger than on any previous occasion

UNIVERSITY COLLEGE, BRISTOL FACULTY OF MEDICINE —At University College, Bristol, on Oct 30th, Sir W Ramsay presented the following prizes and certificates to the successful candidates Winter Session—Medicine prize, S C Hayman Surgery S C Hayman Public health prize, J D Calcott certificate, L Shingleton Smith Senior anatomy prize J W Willcox, certificates, A J Wright, V Green Armytage, R E Thomas, G S Parkinson, and J F Blackett Junior anatomy certificates J M Hammond and P S Tomlinson Physiology, Part I prize J W Willcox, certificates L J Short and R B M Hopkins, Part II prize, R B M Hopkins, certificates J W Willcox, J F Blackett L J Short, F T Boucher, V Green Armytage and E S Goss, Part III prize, H S Rivington, certificates J M Hammond L J Short P S Tomlinson, C H Taylor R N W Biddulph, and E V Connellan Biology prize P S Tomlinson, certificates W T Clarke, W W Morrison A H Dawes and P Sinnock. Chemistry prize W T Clarke, certificate, P S Tomlinson Summer Session—Pathology prize J D Calcott, certificates, A W Richardson and S C Hayman Medical jurisprudence prize, A W C Richardson, certificates, J D Calcott and S C Hayman Operative surgery prize, S C Hayman, certificate L N Morris Midwifery prize, W J H Pinniger, certificates F Shingleton Smith, L Shingleton Smith and L N Morris Practical medicine, Surgery and Midwifery prize L N Morris, certificates, F Shingleton Smith, A N Thomas, W J Pinniger, and F G Bergin Anatomy prize, P S Tomlinson, certificate J M Hammond Practical chemistry prize, P S Tomlinson certificate W Morrison Pharmacology and Therapeutics prize J W Willcox Materia medica prize, E Davies, certificates R J Parnell and S H Kingston

SOCIETY OF APOTHECARIES OF LONDON —The Lord Mayor s Day dinner of the Society of Apothecaries was held at the Society s hall in Blackfriars, London, on Nov 10th the Master of the Society Mr Clarence Cooper, being in the chair, supported by the wardens Mr Albert B Day and Mr J H Jeffcoat Covers were laid for about 100 persons and amongst the guests were Sir W S Church President of the Royal College of Physicians of London Mr J Tweedy, President of the Royal College of Surgeons of England Mr A Gibbs M P, Sir Joseph Fayrer Professor A Macfadyen, Sir Hugh Beevor, Sir William Wilson Sir Trevor Lawrence, Dr F T Roberts Mr S R Atkins, President of the Pharmaceutical Society Mr S F Cowell, Mr Shirley F Murphy, Dr Dawson Williams Mr W Arbuthnot Lane Mr W A Frost Dr A H N Lewers, Mr Andrew Clark, Mr. G H Makins and Dr F de Havilland Hall Mr Cooper, in proposing the toast of "The King," referred to the warm interest taken by His Majesty in medical work and pointed out how it encouraged advancement in scientific research In proposing the toast of ' The Visitors ' Mr Day extended a warm welcome to the President of the Royal College of Physicians of London the President of the Royal College of Surgeons of England, and the other guests This toast was responded to by the Presidents of the Royal Colleges. Sir William S. Church said that there was a close connexion between the Society of Apothecaries and St. Bartholomew's Hospital and for more than two centuries there had been at St. Bartholomew's a resident apothecary, the last being Mr. Frederic Wheeler, to whom he (Sir William Church) had been apprenticed. Mr. Tweedy said that all must respect the useful work done by that Society in the interests of the medical profession. To Mr. Tweedy was also entrusted the office of proposing the toast of "The Society of Apothecaries of London." He said that before the earliest association of Barber Surgeons in London a Society of Apothecaries existed with records reaching back to the Crusades, when the Apothecaries were an active and energetic body. During the terrible plague of London the Apothecaries were about the only persons who remained in the City to attend the sick and the dying. The Society of Apothecaries had fulfilled a very important function in promoting medical education and licensing practitioners. In his opinion the medical student was in danger of being over-educated and he would rejoice to see that Society take a larger share in the future in medical education and qualification. The subject was an economical one as well as educational because the increasing cost of medical education had reached such a degree that a man had to consider whether it was worth while paying for the costly and elaborate training required for the University of London with no further recompense at the end than such as was to be gained in remote country districts. Mr. Cooper, in acknowledging the toast, explained the lines on which the Society had lately been affording opportunities for the progress of medical science.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bailey, Robert Cozens, M.S. Lond., F.R.C.S., has been appointed Assistant Surgeon to St. Bartholomew's Hospital.

Bent, Sidney C. H., M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Evelina Hospital for Sick Children.

Booth-Clarkson, Captain J., L.R.C.P. Lond., L.R.C.S., Reserve of Officers, District Surgeon and Health Officer for Alexandra County, has been appointed a Justice of the Peace for Alexandra County, Natal.

Duncan, W. Henry, L.R.C.P. & L.R.C.S. Edin., has been appointed House Surgeon to Nottingham Children's Hospital.

Greenwood, Alfred, M.D. Vict., D.P.H., Medical Officer of Health of Blackburn, has been appointed Medical Officer to the Blackburn Education Authority.

Hepburn, David, Professor, M.D., C.M. Edin., M.R.C.S., F.R.S. Edin., has been appointed Dean of the Faculty of Medicine of the University College, Cardiff.

Orange, Margaret, L.S.A. Lond., M.D. Brux., has been appointed Lecturer on First Aid and Home Nursing, London School Board, and Clinical Assistant to the Evelina Hospital for Children.

Parsons, E. D., L R C.P. Lond., M R.C.S., has been appointed House Physician to the Evelina Hospital for Sick Children.

Samuel, Henry T., L R.C.P. Lond., M.R.C.S., has been appointed Assistant House Physician to the Cardiff Infirmary.

Simon, David Ap, M.B., B.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for Nantgaredig District of the County of Carmarthen.

Stuart-Low, William, F.R.C.S. Eng., has been appointed Assistant Surgeon to the Central Throat and Ear Hospital, Gray's Inn-road.

Smith, D., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Creetown District of the County of Kirkcudbright.

Timms, A. E., L.R.C.P., L.R.C.S. Edin., has been appointed Assistant House Surgeon at the Cardiff Infirmary.

Wheeler, E. R., M R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Evelina Hospital for Sick Children.

Whitelocke, R. H. Anglin, M.D., M.Ch. Edin., F.R.C.S. Eng., has been appointed Lichfield Lecturer on Clinical Surgery in the University of Oxford.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service.—Examination of Candidates for not less than 30 Commissions in the Royal Army Medical Corps.

Bethlem Hospital.—Two Resident House Physicians (unmarried), for six months. Honorarium at rate of £25 each per quarter, with board, &c.

Birmingham and Midland Free Hospital for Sick Children.—Two Acting Physicians.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street, Birmingham.—Surgical Assistant for six months. Honorarium at rate of 52 guineas per annum.

Brighton, Hove, and Sussex Throat and Ear Hospital, Church street, Queen's-road, Brighton.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

([illegible] Dispensary.—Vacancy on Medical Staff.

[illegible] **for Children and Dispensary for Women**, [illegible] Physician for six months. Honorarium of £25, with board, residence, &c.

Evelina Hospital for Sick Children, Southwark, S.E.—Surgeon to Out-patients. Also Pathologist. Salary 100 guineas per annum.

Hereford County and City Asylum.—Senior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

Hospital for Sick Children, Great Ormond-street, W.C.—House Physici[illegible]s. Salary £20, with board and residenc[illegible]gist and Bacteriologist, non-resident [illegible]r annum.

Liverpool [illegible] House Surgeon. Salary £100 per annum, with board, residence, and washing.

London Lock Hospital.—House Surgeon to the Female Hospital. Salary £80 per annum, with board, lodging, and washing.

Margaret-street Hospital for Consumption and Diseases of the Chest, 26, Margaret-street, Cavendish-square, W.—Pathologist.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160, rising to £1[illegible]0.

New Hospital for Women, Euston-road, N.W.—Clinical Assistant (female) in Out-patient Department.

North-West Lo[illegible] Medical Officer, also [illegible] Salaries at rate of £[illegible] per annum, [illegible] washing.

Paddington-green Children's Hospital, London, W.—Surgeon to Out-patients. Also Pathologist and Registrar. Salary £50.

Royal Free Hospital, Gray's Inn-road, W.C.—Junior Obstetric Assistant (female) for six months. Board and lodging provided.

Royal Waterloo Hospital for Children and Women, Waterloo Bridge-road, S.E.—Surgeon to Out-patients.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Clinical Assistants for six months.

St. Bartholomew's Hospital.—Surgeon.

St. Mary's Hospital Medical School, Paddington, W.—Lecturer on Physiology. Salary £400 per annum.

St. Pancras and Northern Dispensary, 126, Euston-road, N.W.—Honorary Physician.

St. Thomas's Hospital.—Assistant Surgeon.

Sheffield Children's Hospital.—Lady House Surgeon. Salary £70 per annum, with board, lodging, and washing.

Township of Toxteth Park Workhouse and Infirmary, Liverpool.—Assistant Medical Officer. Salary £100 per annum, with board, washing, and apartments.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House Physician for six months. Honorarium of £25, with board and lodging.

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon, unmarried. Salary £100, with apartments, board, and service.

Wolverhampton Union Workhouse, Heath Town, Wolverhampton.—Assistant Medical Officer (resident), unmarried. Salary £130 per annum, with apartments, rations, and washing.

Wrexham Infirmary.—Resident House Surgeon. Salary £80 per annum, with board, lodging, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory Act at Withnell in the county of Lancaster.

Births, Marriages, and Deaths.

BIRTHS.

Dyson.—On Nov. 5th, at 25, Aldersgate-street, E.C., the wife of Malcolm G Dyson, F.R C.S., of a son.

Gairdner.—At Cairo, on the 8th instant, the wife of the Rev. William Henry Temple Gairdner, B.A., a son.

Stephens.—On Nov. 7th, at Elderslie, Hoylake, Cheshire, the wife of J. W. W. Stephens, M.D. Cantab., of a son.

Willcox.—On Oct. 10th, at Frogmore, St. Albans, the wife of W. H. Willcox, M.D. Lond., of a son.

MARRIAGE.

Atkinson—Hicks.—On Nov. 5th, at St. James's Church, Piccadilly, John Parkinson Atkinson, B.A., M.R.C.S., L.R.C.P., to Dorothea, youngest daughter of Charles Francis Hicks.

DEATHS.

Alexander.—On Nov. 3rd, 1903, at Ashford, Middlesex, Ella Harriette, widow of [illegible] Charles Archibald Alexander, M.B. Canta[illegible] Guards, aged 43.

Cradock.—On [illegible] residence, 52, Huskisson-street, Live[illegible] L.R.C.P.I.

Lawton.—On [illegible] 2 years, Herbert Alfred Lawton, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., M. and D.P.H., and late Medical Officer of Health.

Nicholson.—On Nov. 8th, at the Grange, Totteridge, Sir Charles Nicholson, Bart., M.D., D.C.L., LL.D. Cantab. and Edin., aged 95.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET

SIRS,—In the letters that are appearing on the subject of motor-cars we only hear the rosy side of the question and I hope you will allow me to mention a few points on the opposite side, and I can speak from sad personal experience, having had a car and having given it up in favour of the despised horse

1 *Locality*—Cars may be, and probably are, very convenient for long distances between stopping places and long journeys, but when it comes to towns and suburbs they are in my opinion and in the opinion of other medical men to my personal knowledge most unsuitable Usually when making a visit the engine has to be stopped running, as it is impossible to tell how long one will be, and then started again, often giving rise to delay and trouble through some trifling fault, and it is not very conducive to one's good temper to be grinding at a handle in public thoroughfares at a machine which will not start, whilst if the groom or chauffeur starts it, or tries to, both master and man are wandering round endeavouring to find out the fault. With a cart or carriage one would be in the next house by the time the car is ready to go and both seated. If the engine is allowed to run whilst in a house there are the well known and unavoidable smell and noise.

2 *Cleanliness*—I will defy any motorists to keep clean and neat. Whilst running there is the dust, when either at home or on a journey some slight alteration is required—e g, slipping belts, sparking plug fouling short circuiting, or the hundred and one things that may require adjusting; then the quantity of dust, oil, and grease that finds its way on to one's clothes and hands, even through the best of gloves, is incredible and, until one tries to get it off, impossible to conceive and it is somewhat objectionable to go into a bedroom with the hands of an engine room artificer

[illegible] on [illegible] at [illegible] ils [illegible] s, [illegible] alf [illegible] ne one day, I received an urgent call about a mile away to a new and lucrative patient and could not get the engine to start, though it had been all right a quarter of an hour earlier, and when after giving it up as a bad job and having made myself as presentable as possible I took a passing cab to find a rival practitioner in attendance you will understand that there are disadvantages in a motor car.

6 *Physical and mental strain*—I found myself, and others have told me that they experienced it also, the mental strain of driving a car amongst traffic, specially at any rate of speed, and the constant vibration makes the hands tremble and shake Patients and their ailments are plenty to worry about without the extra anxiety of an engine driver.

7. As to the kind of car that is suitable. Electric cars are clean and expensive, but quite unsuitable to any work except in large cities. Steam cars, fairly clean but intricate, have been known to be consumed by fire in the high road. Petrol cars are dirty; noisy, difficult to start, and fairly cheap.

I am, Sirs, yours faithfully,

Nov. 9th, 1903. EQUES.

To the Editors of THE LANCET.

SIRS,—If "*Tramite Recta*" really contemplates habitually driving a motor-car on gradients of one in three (!) I can assure him that his providing the necessary material for a coroner's inquest is merely a matter of time He may do it 10, 20, or 100 times, but sooner or later his engine will stop going up hill, or his brake will fail, or his steering gear will give, or his wheel will touch one bank, shooting his car across the road going down. After any of these occurrences the only other conveyance he will require will be one that is driven very slowly and will in all probability contain several wreaths of flowers bearing sympathetic inscriptions.

I am, Sirs, yours faithfully,

Stratford on Avon, *Nov. 6th*, 1903 *HARRY LUPTON.*

A SERIOUS QUESTION.

To the Editors of THE LANCET.

SIRS,—Dr Robert Jones in his paper read before the Society for the Study of Inebriety on July 15th, 1902, and published in THE LANCET of Oct 25th, 1902, p. 1118, stated that "a still more striking fact is that the death rate from alcohol during the last 15 years has increased by 42 per cent in men and 100 per cent in women" One naturally asks what are the reasons for this great increase amongst women. I beg to suggest that one factor may be that many women at the approach of every menstrual period make a practice, although they are most temperate at other times and many of them pose as "teetotalers," of drinking for two or three nights in succession from half a quartern to one quartern of hot gin each night before retiring to rest, and I have heard it stated that many of the medical attendants of these women are in the habit of recommending this practice Whether this statement is true or not I do not know, but I believe it to be a fact that whether their medical men advise it or not this is the secret practice of many women and young girls even of 15 years old in the middle and lower classes. I suppose that the advantage of this drink is supposed to lie in the diuretic properties of the juniper spirit or oil with which it is flavoured, but could not some equally or more efficacious non-alcoholic drink be made known and generally prescribed?

I am, Sirs, yours faithfully,

Nov. 7th, 1903. A LAYMAN.

THE BRITISH MEDICAL BENEVOLENT FUND.

THE following is a second list of donations received in response to Sir William Broadbent's appeal —

	£	*s*	*d*		£	*s*	*d.*
Mr W. H Patmore Sheehy	10	10	0	Mr. E. B Payne	1	1	0
Dr. C. A. Lee	5	5	0	Mr. J. King Lewis ...	1	1	0
Dr. F. Parsons	5	0	0	Dr E. B Fiennell	1	0	0
Mr Wilson Eager	3	3	0	Dr. J. H. Blight	1	0	0
Dr. S H. Habershon (annually)	2	2	0				

The treasurer is grateful for the response already given to Sir William Broadbent's appeal. Unfortunately the amount of money received still falls far short of the requirements of the fund at the present time and unless the resources of the fund are largely increased the pressing claims which winter always brings will be very inadequately provided for Further subscriptions and donations are urgently needed and may be sent to the treasurer, Dr. S. West, 15, Wimpole-street, London, W.

ADVERTISING 100 YEARS AGO.

THE recent pronouncement of the British Medical Association regarding the appearance of the names of medical men in lay newspapers, referred to in a leading article which appeared in THE LANCET of Nov. 7th, p 1310, makes the following paragraph from the *Belfast News Letter* of 1810 of interest to-day —

> JOHN HOLMES, M.D,
>
> having completed his education in the various branches of his profession, takes the liberty of informing the public that he intends making Colerain the place of his residence, and as a medical practitioner respectfully solicits their notice.
>
> From the ample opportunities which he has had of acquiring an accurate and extensive knowledge of the many important improvements which of late years have been introduced into medical practice by the most eminent of our modern practitioners, he trusts he shall not be accused of presumption by recommending himself as duly qualified to discharge the serious duties of so important a trust with fidelity and success
>
> With much deference Dr. Holmes would intimate that he has paid more than ordinary attention to those affections which are known by the general epithet of fevers and that he still intends to cultivate that most important branch of his profession with the utmost care and industry. He also thinks proper to state that in order to render his knowledge as complete as possible he has dedicated no inconsiderable share of his time and attention to those studies which more especially belong to the province of the surgeon. Colerain, March 16th, 1810.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I shall be glad if any of your readers can tell me of a home suitable for a girl, aged 15 years, who is suffering from spastic paraplegia. The child is helpless and of feeble intellectual development but is not imbecile. Her parents are in very humble circumstances but a small payment might be possible through charitable friends. Efforts to find a home have thus far been ineffectual

I am, Sirs, yours faithfully,

1, Ethelbert-crescent, Margate, Nov. 8th, 1903 F. E. NICHOL.

MAIZE OR INDIAN CORN AS A FOOD.

To the Editors of THE LANCET.

SIRS,—For some time I have at varying intervals tried maize flour or Indian corn as an article of dietary and I believe if only people could be prevailed upon to try it it would be found a valuable addition to our list of cereal foods Unfortunately, in England and Scotland Indian corn is associated with the feeding of poultry and when a prejudice has once been established it is difficult to uproot. People, and more especially the artisan classes, think this particular cereal is food only fit for hens Nothing could be further from the truth Maize in the form of finely milled flour is a pleasant and nourishing food. It is largely employed in America, South Africa, Germany, and now also in Ireland. Here let me emphasise the point that it is the fine meal I mean, for unless this is specially mentioned the dealer will supply the coarse-ground meal uncleaned and unfit for human beings. Indeed, so little is the fine meal known in England that I have been unable to obtain it in a large town like Leeds. The supplies I have hitherto had have come from Ireland *Comparing the cost with that of* flour I find they are about the same, but if maize came into more general use it should be much cheaper than wheaten flour Comparing wheat, maize, and oats as to their nutritive values one finds that in albuminoids the three agree closely. In starch maize is nearly as rich as is wheat and in this agent it is richer than oatmeal. In fat maize is as rich as is oatmeal and this is an important point in the feeding of the poor. Wheaten flour, as is well known, is poor in fat. The composition of the fat of maize is similar in quality to the fat of other cereals, consisting of glycerine and oleic, stearic, and palmitic acids, but it differs in the proportions. Maize fat contains a relatively large quantity of glycerine—namely, 6 46 against 2·8 for oatmeal.

Maize, in my opinion, would find its chief use in England as a porridge. In the form of porridge it has a pleasant sweetish taste and is liked by children. Its richness in fat can be proved by placing a spoonful of the porridge in water when the minute droplets are seen floating on the surface. Maize porridge is in taste very like a semolina pudding. The flour can also be made into cakes, and these are a change from wheaten bread, although one soon tires of this bread by itself. However, it is a variety and the more variety we can get in our food the better it is. At the present day we are getting too much tied down to the use of wheaten bread. I have no need to mention other ways of cooking Indian corn. These suggest themselves to every housewife. Let me say that in the shape of fancy foods people often pay fabulous prices for Indian corn.

I am, Sirs, yours faithfully,
Leeds, Nov. 7th, 1903. J. Gordon Sharp, .D. Edin.

THE WILLIAM CADGE MEMORIAL.

To the Editors of The Lancet.

Sirs,—We shall be obliged if you will insert the following final list of subscribers to the above memorial.

We are, Sirs, yours faithfully,
W. H. Day.
Norwich, Nov. 9th, 1903. Michael Beverley.

London:—
Sir Henry Thompson, Bart.
Sir Joseph Dalton Hooker, G C.S.I., C.B.
Sir Victor Horsley.
Mr. John Tweedy.
Mr. Edgcombe Venning.
Mr. Richard Barwell.
Mr. C. A. Ballance.
Dr. Sidney Ringer.
Dr. J. Hughlings Jackson.

Dr. Andrews, Norwich.
Dr. Crooke, Norwich.
Dr. H. Muir Evans, Lowestoft.
Dr. A. Marshall, Lowestoft.
Dr. H. Blake, Yarmouth.
Dr. John T. Skrimshire, Holt.
Mr. B. Maurice Hughes, Wymondham.
Mr. H. Back, Acle.
Mr. S. M. Hopson, Dereham.
Dr. John Bately, Gorleston.
Dr. C. B. Plowright, Lynn.
Mr. E. T. Prior, Loddon.
Mr. G. E. Deacon, Hethersett.

THE USE OF PETROLEUM.

To the Editors of The Lancet.

Sirs,—I shall be glad if any of your readers can inform me as to the nutritive value of petroleum administered internally and its mode of action. Is it simply a food, to be absorbed and utilised as such, or is its action purely antiseptic to pave the way and to improve the tone for the better digestion of normal food? Also, what is the relative nutritive value of the animal, vegetable, and mineral oils?

I am, Sirs, yours faithfully,
Nov. 9th 1903. C. W. S.

THE CIGARETTE CRAZE.

To the Editors of The Lancet.

Sirs,—In course of several thousands of inductions of anæsthesia I have found that in a certain percentage of cases—young men with no appreciable lung trouble or previous history of such—the inspiration of ether at once causes intense irritation, excess of secretion, and cyanosis. If the ether be pushed the patient after many long spasms is anæsthetised but remains a bad colour, and on auscultation "the air-way" down to the small capillaries seems partially filled with secretion and the patient "takes the anæsthetic badly." A similar state of affairs is found when the ether tension rises if the gas-ether method of induction be used. On investigating these cases I found that all of them had been heavy cigarette smokers and inhaled the smoke also.

Of late I have administered chloroform to all patients who confessed to the excessive use of the cigarette and have always found the irritation less, although on auscultating the fully anæsthetised patient one frequently finds moist crepitations audible over the bases of the lungs and occasionally in the axillæ and the front of the chest. These crepitations were not present before induction and are not found in normal cases unless there has been some previous lung trouble or irritation, so I think it is fair to assume that the respiratory tract has not (to put it mildly) been improved by the inhalation of the cigarette smoke.

I am, Sirs, yours faithfully,
J. Reginald Bentley, M.B., B.C. Cantab., &c.,
late House Physician, &c., Royal Berks Hospital,
Barrow, Hull, Nov. 5th, 1903. Reading.

QUACKERY IN HIGH PLACES.

A correspondent sends us a copy of an advertisement of a liniment which appears in one of the best known London papers. The advertisement states that the wife of the Commander-in-Chief has written to the proprietors of the nostrum in question to say that she finds it most excellent and that she incloses 2*s*. 9*d*. The Countess Roberts, through the manifold excellencies of her husband, has attained to a high place in society. We feel that she ought not to be entrapped by such a statement as "—— liniment cures rheumatism in five minutes." It is the credulity of people in conspicuous positions which leads the public to support so many charlatans. The army will follow Lord Roberts anywhere and it is not unlikely that the wives of the army may follow his wife. The Countess Roberts is rich and the 2*s*. 9*d*. is nothing to her, but to the wife of a soldier with a few pence a day 2*s*. 9*d*. is a large sum. Mrs. Tommy Atkins may be persuaded to imitate the example of the Countess Roberts and thus to pay 2*s*. 9*d*. for an application the equivalent of which could have been supplied at much less cost by a medical man or by a druggist on a medical man's prescription.

SPHYGMOGRAPHS.

To the Editors of The Lancet.

Sirs,—I should esteem it a great favour if one of your readers would inform me what sphygmograph, in his opinion, would be preferable for a country practitioner as I am rather doubtful what form to purchase. I am, Sirs, yours faithfully,
Nov. 10th, 1903. A Country Practitioner.

◆

Y. Z.—Our correspondent has forgotten to inclose his name and address.

Inquirer does not make it clear whether he is a medical man.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho-square (2 p.m.), Royal Orthopædic (2 p.m.), City Orthopædic (4 p.m.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed "To the Manager "*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423, Strand W C , are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		*TO THE COLONIES AND ABROAD*	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues , and Agents are authorised to collect, and do so collect from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES 423, STRAND, LONDON, ENGLAND

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; *copies only* should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, *Paris*.

An Address

ON

THE IDEAL PHYSICIAN: HIS EARLY TRAINING AND FUTURE PROSPECTS.

Delivered to the Students of the Royal College of Surgeons in Ireland on Nov. 2nd, on the Opening of the Medical Session 1903–04,

BY, SIR LAMBERT H. ORMSBY, M.D. DUB.,
PRESIDENT OF THE COLLEGE.

GENTLEMEN,—About this time last year and in this place I had the honour and privilege, as President, of bidding you welcome on entering upon the study of one of the most arduous and yet most noble of professions. To-day I again bid you welcome, those particularly who are entering on the study of medicine as well as those who are resuming study. The latter I would ask to start with redoubled energy after their long and well-earned holiday and so give both a healthy stimulus and bright example to their junior fellow students.

It is the custom with some to condemn addresses and in many medical schools they are falling into abeyance. I am of opinion, however, that a short address introductory to the session about to commence is of great service to those beginning the profession, as it marks with emphasis the starting point of the student's career, and I would be very sorry indeed to see the custom given up here where it has existed for so many years. The selection of the topic of my address to day I can assure you was a great mental puzzle, anxious as I was to arrange my subject so as to say something interesting and suitable to all If I merely drew up a sermon full of fatherly advice for the first year students, telling them that if they wanted to succeed in the battle of life they must be zealous and industrious, it would in the abstract, be strictly true; still this oft repeated tale would be *anything but interesting to the senior students* who have frequently heard me and others on the same subject Then *I knew we should have a number of qualified brethren*, senior and junior, present, and they would hardly go to the trouble of listening to me through high-sounding platitudes with a sprinkling of poetry to make it read well in pamphlet form. I therefore select for my address to day the following subject:—"The Ideal Physician: His Early Training and Future Prospects"

To be an ideal physician should be the aim of every man who embraces medicine as a profession. Everyone is not gifted with the same qualifications for a successful career Some few indeed may be born with exceptional ability but at the same time endowed with a rough overbearing manner yet by sheer determination they may force their way into the front ranks of their profession But such disregard for the feeling of others and such lack of politeness must always tell against their success in the long run Others adopt this Abernethian style from ignorance. I regret to say it appears to be an age when young men are prone to pay but scant courtesy to their seniors, under the mistaken idea that having been born in a more enlightened age they could not possibly learn anything worth knowing from those who have gone before. This is a popular fallacy and the outcome of youthful presumption and want of experience and common sense, for the more a medical student or young practitioner learns the more he appreciates those master minds who have *been the pioneers of his profession. The early training of* the ideal physician, as for any other ideal, must be undertaken with very great care It is, in fact a preparation for a great and serious struggle, a most momentous battle A youth must start as a student determined to succeed Fix, then, in your own minds some successful model and ascertain the means by which he succeeded, whether by tact, industry, skill, or a combination of all these, and then strive with all your might to acquire the same qualities Take care in starting that you are equipped with all the necessary armour and weapons for the encounter upon which you have entered. Be industrious, punctual, cheerful, kindly, courteous to your seniors, respectful to your teachers, and prune off those small objectionable asperities which might hereafter be the means of retarding your progress. And above all avoid that sorry band of wasters and drifters whose ways and means are so well known to you all. Let your one aim and end be always to achieve the enviable reputation of a good physician and a courteous gentleman. As I stand here I see before me a body of stalwart young men, burning with the generous sympathies of youth, strong with robust qualities both mental and physical, standing in the shadow of this old and respected seat of learning, upon the brink of the arena into which they are so soon to enter. So let me *now briefly allude to your future prospects.* You will ask me, what are your future prospects? In answer I may mention the Navy, the Army, the Indian Medical Service, foreign appointments, ship surgeoncies, the Irish Poor-law medical service, and lastly, private practice. Of those I fear I shall only have time to make a brief allusion to three. Last year I spoke at length upon the favoured conditions of the home Army Medical Service as a career, and I am still in favour of this service, notwithstanding there are yet a few grievances in the Royal Army Medical Corps to be remedied. To commence with

THE NAVAL MEDICAL SERVICE.

This service is the oldest service of all and ought to be one of the most popular But it is not popular and you may ask me why Well, I will try to enumerate a few of the defects of the Royal Naval Medical Service up to six months ago and to point out certain grievances in the recent regulations which have been remedied.

Grievance No 1, late promotion—At present the average age of a surgeon entering the Naval Medical Service is 25 years; he serves until he is 37 years before he becomes a staff surgeon and 45 years before he becomes a fleet surgeon, and he may be selected for the higher branches at about the age of 52 years. No other branch of the navy has to wait so long to attain corresponding rank; comparison of ages with the executive or combative branch of equal relative rank will clearly show this. Surgeons, 25 years; staff surgeons, 37 years; fleet surgeon, 45 years; deputy inspector-general, 52 years. *Lieutenant, 21 years; lieutenant after eight years'* service, 29 years; commander, 33 years; and captain, 40 years. Under these conditions the naval medical officer may be placed in the position of having to ask leave from a man who is considerably his junior in the service. To make the service popular I consider promotions to staff surgeons should be after eight years' service and to fleet surgeons after 16 years' service. This change, I am informed on the best authority, is to be made in regulations which will appear in a very few weeks.

Grievance No. 2, foreign service.—It is urgently needed that some reform *should be made* as to the *regulation of* home and foreign service. At present a staff surgeon returning home after three years' foreign service (which may be in the unhealthy climates of the East Indies or West Coast of Africa for which he gets no extra pay) after six weeks' leave (that is only 14 days for each year spent abroad) is most probably appointed to either the home, cruiser, or Channel squadrons. These fleets have no fixed port and are continuously cruising about. Consequently the staff or fleet surgeon if married sees little or nothing of his wife and family and after from 18 months to two years of this so-called home service he is again sent abroad for another term of foreign service. To remedy this there should be a fixed regulation that every medical officer returning from a foreign station should *be entitled to a period of shore* or harbour service.

Grievance No. 3, compulsory half pay—This has by no means been done away with; the great objection is not so much the loss of annual income, which is bad enough, but also the loss of time. The time spent on half pay has to be made up before retirement

Grievance No 4.—Another grave injustice is that a number of medical officers wait patiently until they have completed 20 years' full pay service (the time spent on half pay having to be made up), this being the earliest period when they can retire with a pension But when this long-looked-forward-to time has arrived it sometimes happens that *the unfortunate medical officer is serving abroad* He is informed on applying for retirement that his services cannot be spared even if he offers to pay his own passage home and his successor's passage out He is therefore liable to be retained on a foreign station for a period of three years' longer.

Grievance No 5, control of sick berth staff.—The principal medical officers of naval hospitals have no power to deal with breaches of discipline on the part of the sick staff that serves under them. An inspector-general, who is supposed to rank with a rear admiral, before he can get a man punished has to report him to the executive authorities of the local depôt and much time is wasted before the charge is heard or the offender punished. Surely the sick bay staff ought to be under the control of the naval medical officer just as the men of the Royal Army Medical Corps are under the control of their officers in the same corps.

Grievance No. 6, medical guard.—It is the recognised custom in the present day where two or more ships are in harbour together for the naval medical officers to take it in turn day about to keep medical guard. This means that a medical officer of the ship having the medical guard has to remain on board his ship to be ready to go to any emergency case in any of the other ships in harbour. Although this is practically the custom and works admirably, still it is not as yet embodied in the King's regulations and the result is that some captains still insist on always having one of the two medical officers belonging to their ship on board, although the medical officer of the guard is close alongside and capable of being on board in five minutes on signal being made for him. To be kept on board every alternate day for the whim of an individual captain is very galling, more especially as it is only done in one or two ships in a fleet. To obviate this grievance it should be clearly laid down in the regulations that medical guard is to be recognised in all ships.

There are many other petty disadvantages which irritate the naval medical officer that a little re-arrangement could easily remedy without any loss of discipline or efficiency. For instance, there is no encouragement of individual responsibility at medical surveys. An inspector-general ranking as rear-admiral is forced to sit under the presidency of a post-captain or even a commander who is years his junior in service. Of course, I do not wish to deny that the captain should command his own ship, but I do think that if the status and position of the naval medical officer are to be upheld he should have entire control of the sick and the sick-berth staff and should be able to punish them for breach of discipline in their special work should necessity arise, the same as in the Royal Army Medical Corps. A new set of regulations has just been issued and some of the matters I have complained of have been remedied, but many grievances still exist which, if not removed, will act as a barrier to the entrance of efficient men into the service. The present Director-General, Sir Henry F. Norbury, K.C.B., has done more to improve the service than any of his predecessors. I know he has the interests of the service at heart and is only too anxious to see his branch brought into efficiency and popularity, but I have no doubt that when he suggests improvements he is stopped by the Treasury which will not sanction any improvement that costs additional money. The Government yearly expends millions on the building of warships intended to inflict death and suffering on our fellow men. How much more in the cause of humanity should they be willing to expend a few thousands on a branch of the service whose mission it is to prevent, or to cure, disease and to alleviate the suffering inflicted by shot and shell on their fighting men. If the distinguished Director-General, Sir Henry F. Norbury, fails to induce the Admiralty and the Treasury to amend these grievances by mild expostulation these authorities will be forced in the long run to yield because men will not go into a service where discontent and injustice are maintained. In the end the Admiralty will have to follow the example of the army and at once accede to the views of an energetic and independent civilian advisory board constituted on the same lines as the Royal Army Medical Corps but called in the navy the Medical Consultative Board. The Royal Army Medical Corps now gets plenty of well-qualified candidates but in the Naval Medical Service there is a deficiency of over 50 surgeons. But I hope before long to see all these grievances mentioned removed and good and efficient men once more induced to enter it. I would now like to say a few words about another service which has somewhat grown into disfavour.

THE INDIAN MEDICAL SERVICE.

I read in THE LANCET an official memorandum dated India Office, October 1903, in which will be seen certain alterations effected for the improvement of the service. First, I find by the new regulations that the pay of the Indian military medical officer is increased although the increase sanctioned is not very large. A lieutenant's commission will in future date from the day on which his course of instruction commences and he may be promoted to captain on completion of three years' full-pay service, the same as the Royal Army Medical Corps, but he will be required after 18 months' service to pass an examination in military law and military organisation. The unemployed pay of a lieutenant in India will be in future Rs. 420 a month instead of Rs. 350, while when placed in permanent medical charge of a regiment his pay will be Rs 500 in place of Rs 450. On promotion to captain if in substantive charge he will receive Rs. 550 in place of Rs. 450. After seven years' service there is an increase from Rs 600 to Rs. 650 and after 10 years' service from Rs. 600 to Rs. 700. The pay of a major after 15 years' service who is in substantive charge is increased from Rs. 800 to Rs. 900 and of a lieutenant-colonel from Rs. 1000 to Rs. 1250. A lieutenant-colonel who has 25 years' service will in future receive Rs. 1300 if in substantive charge and if specially selected for increased pay Rs. 1400. The pay of one surgeon-generalship is raised from Rs. 2700 to Rs 3000. In justice to the officers now serving it is hoped that the regulations will be retrospective as far as they are concerned and that the regulations will have a retrospective effect from the date of the increased pay under the recent warrant granted to officers of the Royal Army Medical Corps serving in India, to which charge I alluded in my address last year. Following the precedent set of the case of the Royal Army Medical Corps it is now provided that specialist pay at the rate of Rs 60 a month will be granted to officers below the rank of lieutenant colonel who may be appointed to certain posts, and another clause provides that extra furlough may be granted to officers desirous of pursuing special courses of study at the rate of one month's furlough for each year's service up to 12 months in all. There are other important improvements set out in this memorandum, but there are grievances and drawbacks still remaining. When these are remedied I believe the service will be popular again and many efficient young qualified men will be eager to enter it. The next and last service I have to allude to is nearer home. It is

THE IRISH POOR-LAW MEDICAL SERVICE.

Last year I thought I said all that the head of a college could possibly say to you on the subject. But 12 months have proved to me that if the Poor-law medical service officers are to be supported in their manly fight against injustice and dishonour it behoves all those in any position in the profession to speak in season and out of season against the gross treatment which is meted out day by day to our brethren whose unfortunate lot it is to serve in the Irish Poor-law medical service. The Right Hon. George Wyndham, M.P., the able Chief Secretary for Ireland, has since this time last year piloted a most successful Bill through Parliament for the "better union of hearts" and for the settlement of the land question and for the satisfaction and contentment of all parties concerned. But if I am asked what has been done for the Irish dispensary medical officer I regret to be obliged to say nothing. Now let me enumerate again the grievances and disabilities which an Irish dispensary medical officer labours under at the present time, as related to me by one who has been an Irish dispensary medical officer for over 30 years. His first and most pressing grievance is that in many instances the salary is not sufficient to pay the expenses of working the district. Then the law declares him qualified for superannuation but leaves him entirely in the hands of men who are a changing body, liable to be swayed by the transient influences of the moment and who, perhaps, resent a dispensary medical officer as being in the words of a popular M.P., a "blue-blooded official." When such is the feeling of a Member of Parliament towards our dispensary medical officers one can easily guess in what estimation he is held by the rank and file. The dispensary officer becomes sick and tired of the everlasting abuse showered upon his colleagues at the different weekly meetings of the boards of guardians throughout the country and the treatment of the Local Government Board is no better. They heap new duties on their medical officers and when for once a generous and reasonable board of guardians grants an increase of salary they will not sanction it. Then the mode of election is corrupt root and branch. Think for a moment of the position involved in a medical man having to solicit the votes of members of boards when he is fully conscious that the most inexperienced member of the profession who had local or political influence would beat the President of the Royal College of Surgeons for a dispensary or union if he were a candidate for one

The pressing grievances of the service are therefore narrowed down under six heads 1 Insufficient salaries, which should be raised to at least £200 a year 2 Travelling expenses A medical officer ought not to be compelled to pay the travelling expenses incurred in the discharge of his public duties No other service is asked to do so without payment 3 Annual holidays To amend dispensary rule 28 so as to give to medical officers the leave the Local Government Board intended as a matter of right they should have—viz, a full month's holiday in the year 4 Incidence of expense To repeal Clause 6 of the Local Government Amendment Act so as to permit the recoupment from Imperial sources of the full half of the salaries paid to medical officers and not to limit it, as it does now, to the salaries previously paid 5 Superannuation That superannuation to medical officers be paid on the civil service scale and that it should be mandatory and not optional 6 Mode of election This should be placed under civil service rules and each candidate should enter the service by competition after examination

The amelioration of the present conditions rests with yourselves Many of you will be shortly qualified, vacancies occur nearly every week, but I urge you in the strongest manner to refuse to enter a service which imposes such *degradation on its officials, for never before in the history of* Ireland has the service risen as one man to revolutionise old traditions by joining the Irish Medical Association and so enrolling recruits who before were afraid to utter one word of complaint lest dismissal should follow You ought to prefer to break stones on the roadside sooner than enter a service which employs you on starvation terms and the recreants who are now mean enough in face of such warning to compete for dispensaries at a lower salary than £200 a year deserve to be regarded as unworthy of the name of men If they are subsequently treated badly it is only the proper punishment of persons so far forgetful of the duty they owe to their profession and the respect they owe to themselves I am well aware of the responsibilities I incur as President of this College in speaking in such condemnatory terms of a service even though I believe it to be the worst in Europe *But I urge you to stick together Become members* of the Irish Medical Association Be determined and the Government must give way if the sick poor are to be properly relieved and the service is to be made efficient I would also impress on those of you who will soon be qualified the necessity of joining as members

THE ROYAL MEDICAL BENEVOLENT FUND OF IRELAND,

an object to which every practitioner should at once begin to subscribe It is in fact, a form of personal insurance which, like the widow's cruse of oil, will never fail to be of use and advantage None can tell when adversity will overtake them in the form of loss of money or post through ill health or death and it is comforting to know that through your being a subscriber to the Medical Benevolent Fund before such calamity overtakes you the committee will always give your *wife* and children preference Let the *first money* therefore that you earn after qualification be handed to the Royal Medical Benevolent Fund and lay up there a treasure which in need and distress will be at the disposal of those who are near and dear to you

Another piece of advice I will give you The moment you are a member of the profession join a

MEDICAL DEFENCE ASSOCIATION

It only costs 10*s* a year and may be of vast importance to you later in the practice of your profession The value of *insuring against attacks which are often made against* medical men by unscrupulous persons for the purpose of levying blackmail is well known And there is no doubt that if all members of the profession would join the Medical Defence Union many legal actions and many cases of threatening would be done away with A medical man in this city who had a personal charge levelled against him by a former patient was mulcted by a large amount in defending his character against an unfounded charge If he had been a member of the Medical Defence Union the case would have been taken up by its solicitor and defended by its funds Members of the profession are liable at any moment to be assailed by the attacks of evil disposed persons and it behoves all those who value their reputation to prepare for, and to insure against, such a contingency

ABSENCE OF STATE RECOGNITION FOR THE PROFESSION

We must also continue to fight against ignorance and misconception until the general masses are educated to understand the social position which the profession and its members ought to occupy One depreciating influence is the absence of suitable State recognition for the leaders of medicine and surgery In the constitution of our governmental system there should be (and it is *imperatively called for) the appointment of a Minister* of Health or Sanitary Science who should occupy a seat in the Cabinet only to be filled by a physician or a surgeon of eminence and ability, not bestowed upon some worn out practitioner when his energies are effete and his brains are past their work My suggestion may be utopian but if England intends to take a creditable place in the future among the great nations of the world she will set her house in order, for government in the present day and government a hundred years ago are very different matters Scientific medicine must and will take an exalted position in the world when the component parts of the great ship of State are properly constituted The profession of law with its legal peers and lord chancellors, the army and its military lords, and the Church with its spiritual peers must, in justice make room for their Cinderella sister—Medicine *Therefore, the Minister of Health and Sanitary Science* must be an appointment in the near future I presume that there is no one among us who will doubt my assertion that the entire community from the peer to the peasant stands indebted to scientific medicine and surgery Have not all our investigations from the earliest times been directed in the most unselfish manner for the preservation of man's best interests—viz, health and the alleviation of human suffering? Again, the Privy Councils of England and Ireland have been largely composed from time immemorial of lawyers, judges, military men, divines, and peers of the realm, but medical men have been omitted from the list of these supreme advisers *of the executive* Would anyone with a grain of sense give the reason of this? Why should the leaders of our profession not be entitled to be right honourables as well as many other men far inferior, it *may be, to them in birth, position, and scientific attainments?* On what grounds are we excluded as a class? *Simply, I would say, because we as a body have been over*modest in asserting our claims for public recognition as exponents of sciences that are yearly becoming more and more important to the well being of the community

I have mentioned the word "ideal" in describing a physician, let me tell you in a few words what I mean by the term The profession of a medical man is a noble one and should ennoble those who practise it, deepening the sympathies and idealising the life No man knows better the frailties of his *fellow* creatures than the practitioner—no man has more reason perhaps to think pitifully or severely or even contemptuously of mankind But there is no man more broad in his charity, more lenient in his judgments, than the ideal medical man He bears everything, yet he betrays no confidence In many families the medical man is held in as great love and reverence as the priest He is with them in trouble and in joy and from his lips issue the fiats of life and death He must bend his ear to catch the first wailing cry when the infant takes up the burden *of life* and *the last tired sigh* when the old man lays it down He has to wrestle with the great foe of humanity at every turn, to him the blanched mother may owe her fluttering life when giving birth to another, it is he who when friends are paralysed with fear of contagion, must face the hideous features of cholera, *typhus fever and small pox*, he must show a calm front to the demands made upon his vital energies and the exaggerated expectations formed of his power to aid, while science itself stands humbled and impotent in the presence of death With all his deep learning the ideal medical man is modest, with all his knowledge of the world he is tolerant he is wise as well as witty gentle as well as powerful a tower of strength to the weak, and ever on the alert to shield the reputation of a brother practitioner It is a life of splendid opportunities for good if lived as the ideal physician may live it and it is open to you all to aspire at least to that ideal

Grievance No 5, control of sick berth staff.—The principal medical officers of naval hospitals have no power to deal with breaches of discipline on the part of the sick staff that serves under them. An inspector-general, who is supposed to rank with a rear admiral, before he can get a man punished has to report him to the executive authorities of the local depôt and much time is wasted before the charge is heard or the offender punished. Surely the sick bay staff ought to be under the control of the naval medical officer just as the men of the Royal Army Medical Corps are under the control of their officers in the same corps.

Grievance No. 6, medical guard.—It is the recognised custom in the present day where two or more ships are in harbour together for the naval medical officers to take it in turn day about to keep medical guard. This means that a medical officer of the ship having the medical guard has to remain on board his ship to be ready to go to any emergency case in any of the other ships in harbour. Although this is practically the custom and works admirably, still it is not as yet embodied in the King's regulations and the result is that some captains still insist on always having one of the two medical officers belonging to their ship on board, although the medical officer of the guard is close alongside and capable of being on board in five minutes on signal being made for him. To be kept on board every alternate day for the whim of an individual captain is very galling, more especially as it is only done in one or two ships in a fleet. To obviate this grievance it should be clearly laid down in the regulations that medical guard is to be recognised in all ships.

There are many other petty disadvantages which irritate the naval medical officer that a little re-arrangement could easily remedy without any loss of discipline or efficiency. For instance, there is no encouragement of individual responsibility at medical surveys. An inspector-general ranking as rear-admiral is forced to sit under the presidency of a post-captain or even a commander who is years his junior in service. Of course, I do not wish to deny that the captain should command his own ship, but I do think that if the status and position of the naval medical officer are to be upheld he should have entire control of the sick and the sick-berth staff and should be able to punish them for breach of discipline in their special work should necessity arise, the same as in the Royal Army Medical Corps. A new set of regulations has just been issued and some of the matters I have complained of have been remedied, but many grievances still exist which, if not removed, will act as a barrier to the entrance of efficient men into the service. The present Director-General, Sir Henry F. Norbury, K.C.B., has done more to improve the service than any of his predecessors. I know he has the interests of the service at heart and is only too anxious to see his branch brought into efficiency and popularity, but I have no doubt that when he suggests improvements he is stopped by the Treasury which will not sanction any improvement that costs additional money. The Government yearly expends millions on the building of warships intended to inflict death and suffering on our fellow men. How much more in the cause of humanity should they be willing to expend a few thousands on a branch of the service whose mission it is to prevent, or to cure, disease and to alleviate the suffering inflicted by shot and shell on their fighting men. If the distinguished Director-General, Sir Henry F. Norbury, fails to induce the Admiralty and the Treasury to amend these grievances by mild expostulation these authorities will be forced in the long run to yield because men will not go into a service where discontent and injustice are maintained. In the end the Admiralty will have to follow the example of the army and at once accede to the views of an energetic and independent civilian advisory board constituted on the same lines as the Royal Army Medical Corps but called in the navy the Medical Consultative Board. The Royal Army Medical Corps now gets plenty of well-qualified candidates but in the Naval Medical Service there is a deficiency of over 50 surgeons. But I hope before long to see all these grievances mentioned removed and good and efficient men once more induced to enter it. I would now like to say a few words about another service which has somewhat grown into disfavour.

THE INDIAN MEDICAL SERVICE.

I read in THE LANCET an official memorandum dated India Office, October, 1903, in which will be seen certain alterations effected for the improvement of the service. First, I find by the new regulations that the pay of the Indian military medical officer is increased although the increase sanctioned is not very large. A lieutenant's commission will in future date from the day on which his course of instruction commences and he may be promoted to captain on completion of three years' full-pay service, the same as the Royal Army Medical Corps, but he will be required after 18 months' service to pass an examination in military law and military organisation. The unemployed pay of a lieutenant in India will be in future Rs. 420 a month instead of Rs. 350, while when placed in permanent medical charge of a regiment his pay will be Rs 500 in place of Rs 450. On promotion to captain if in substantive charge he will receive Rs. 550 in place of Rs. 450. After seven years' service there is an increase from Rs 600 to Rs. 650 and after 10 years' service from Rs. 600 to Rs. 700. The pay of a major after 15 years' service who is in substantive charge is increased from Rs. 800 to Rs. 900 and of a lieutenant-colonel from Rs. 1000 to Rs. 1250. A lieutenant-colonel who has 25 years' service will in future receive Rs. 1300 if in substantive charge and if specially selected for increased pay Rs. 1400. The pay of one surgeon-generalship is raised from Rs. 2700 to Rs 3000. In justice to the officers now serving it is hoped that the regulations will be retrospective as far as they are concerned and that the regulations will have a retrospective effect from the date of the increased pay under the recent warrant granted to officers of the Royal Army Medical Corps serving in India, to which charge I alluded in my address last year. Following the precedent set of the case of the Royal Army Medical Corps it is now provided that specialist pay at the rate of Rs. 60 a month will be granted to officers below the rank of lieutenant colonel who may be appointed to certain posts, and another clause provides that extra furlough may be granted to officers desirous of pursuing special courses of study at the rate of one month's furlough for each year's service up to 12 months in all. There are other important improvements set out in this memorandum, but there are grievances and drawbacks still remaining. When these are removed I believe the service will be popular again and many efficient young qualified men will be eager to enter it. The next and last service I have to allude to is nearer home. It is

THE IRISH POOR-LAW MEDICAL SERVICE.

Last year I thought I said all that the head of a college could possibly say to you on the subject. But 12 months have proved to me that if the Poor-law medical service officers are to be supported in their manly fight against injustice and dishonour it behoves all those in any position in the profession to speak in season and out of season against the gross treatment which is meted out day by day to our brethren whose unfortunate lot it is to serve in the Irish Poor-law medical service. The Right Hon. George Wyndham, M.P., the able Chief Secretary for Ireland, has since this time last year piloted a most successful Bill through Parliament for the "better union of hearts" and for the settlement of the land question and for the satisfaction and contentment of all parties concerned. But if I am asked what has been done for the Irish dispensary medical officer I regret to be obliged to say nothing. Now let me enumerate again the grievances and disabilities which an Irish dispensary medical officer labours under at the present time, as related to me by one who has been an Irish dispensary medical officer for over 30 years. His first and most pressing grievance is that in many instances the salary is not sufficient to pay the expenses of working the district. Then the law declares him qualified for superannuation but leaves him entirely in the hands of men who are a changing body, liable to be swayed by the transient influences of the moment and who, perhaps, resent a dispensary medical officer as being in the words of a popular M.P., a "blue-blooded official." When such is the feeling of a Member of Parliament towards our dispensary medical officers one can easily guess in what estimation he is held by the rank and file. The dispensary officer becomes sick and tired of the everlasting abuse showered upon his colleagues at the different weekly meetings of the boards of guardians throughout the country and the treatment of the Local Government Board is no better. They heap new duties on their medical officers and when for once a generous and reasonable board of guardians grants an increase of salary they will not sanction it. Then the mode of election is corrupt root and branch. Think for a moment of the position involved in a medical man having to solicit the votes of diet, notably after bread or other starchy food had been allowed, and 23 per cent. followed on, and presumably were due to, the prescription of castor oil or of enemata to relieve constipation. Thus 58 per cent. of cases of relapse dated from some change in treatment. I am aware that some competent authorities will, and do, dispute my deductions, but I am convinced of the correctness of my views—viz., that any sudden change in dietary, such as from beef tea and milk, which the patient may have been previously subsisting on, to bread and butter, or to farinaceous pudding, is not without considerable risk. I am, however, desirous of fortifying or disproving this statement by the analysis of a larger number of cases of typhoid fever which I hope to obtain from the registrar's records of this hospital. So far it is a firmly established conviction with me that many relapses are attributable to the sudden change in diet. My house physicians have recognised this danger after I have pointed it out to them and have shown me cases in support of my contention. It would require too much time were I to quote examples, although I should have no difficulty. It will suffice if I say that a fresh access of fever occurred in individual cases on the day following when "mixed diet," "extras," "chicken," "fish," or a "copious draught of milk" appeared on the diet sheet.

Recrudescence is a different clinical condition. I regard it as an abortive attempt at a relapse. The fresh access of febrility is sudden, often alarming, but as a rule evanescent, lasting only three or four days at most. It occurs somewhat like this. The patient has been slowly recovering in strength, the temperature has been at or below the normal line for some few days, when an evening observation by the nurse discovers a temperature of, say, 102° or possibly 103° F., and the medical attendant is summoned. The constitutional symptoms are not commensurate with the degree of febrility, so much so that one at first seems sceptical about the thermometrical record and imagines that an error has been made. But on placing the thermometer again it is found that it still records the febrile temperature, that the skin is pungent, that the tongue is somewhat dry, and that the pulse and respiration are somewhat accelerated. The patient is again placed on his fever diet and regimen and in a few days the temperature falls to the normal line, the descending curve during the last 24 hours being often as precipitous as was the ascending one recorded on the evening from which the recrudescence dated. These recrudescences are most interesting clinical phenomena. They bring alarm in their train notwithstanding that our knowledge tells us that there is no great danger. But their chief interest possibly lies in the speculation as to their causation. I have most frequently noted them in those cases in which constipation was a marked feature during the decline of the fever. This constipation may continue into the apparently convalescent stage, and in order to counteract the distress which the loaded large intestine affords the practitioner has probably, and quite justifiably (if I may offer a criticism), prescribed an enema or a dose of castor oil. The evacuation which results is often followed by a sudden and abrupt rise in temperature. So frequent is this observation that many of my house physicians have already noted it and verified the accuracy of this clinical phenomenon. The actual cause or rationale of this recrudescence is not so easy of explanation. For my part I have always regarded it as due to a disturbance of the fæcal masses in the large bowel, by which peristalsis is increased in the whole of the intestinal canal and new toxins are liberated. The toxins produce a temporary or abortive febrility, the patient being practically immune owing to the recent attack of fever through which he has passed. One may compare it to the slight local irritation and constitutional disturbances which occur when the vaccine virus is inserted into the blood of a person already protected by previous inoculation.

Grave symptoms.—It is obvious to all of us that great difficulty must present itself in the subject of prognosis. The disease in one individual may apparently be running a mild course when the sudden onset of severe hæmorrhage places the patient in jeopardy. Another case may have passed through a severe initial attack and when recovery appears in sight a relapse occurs which terminates fatally. But so far as my observations go I would ask you to bear in mind three symptoms, any one of which occurring during the course of the fever should lead us to regard the case as one of considerable gravity. I refer to tremors, delirium, and a persistently high evening temperature (from 104° to 105°). Of course, I am disregarding for the moment the catastrophe of perforation. Muscular tremors, denoting as they do intense exhaustion, are also associated in my mind with deep ulceration of the intestine. This I have verified in a goodly number of post mortem examinations. It may be that the intense exhaustion and the muscular tremors are but indications of the severity of the intoxication and therefore of the consequent deep ulceration. But I am convinced that marked tremor is an indication of extensive destruction of intestinal tissue. Delirium also I regard as an unfavourable sign, especially when it occurs during the day as well as through the night. This is a comparatively rare symptom in our wards unless the case be a very severe one. It is recorded more frequently in German clinics and is one reason why our visitors from the continent regard the type of typhoid fever as seen in their cities as more severe than that in London. A persistently high evening temperature is also a symptom of gravity. Without going into figures I will only give you this experience—viz., that in patients who have presented at any date during the course of their illnesses a temperature of 105° and upwards the death rate is very high. Many (happily not all of them) die either during the primary fever or during a relapse to which they apparently are prone, be we as careful as we may.

A low reading of the temperature requires a few words. It is obvious to you all that if the index of the thermometer shall have been shaken down below "normal" temperature there can be no error in a high reading, whether it be 103° or 106°. Heat alone will cause the mercury to rise to this height, always supposing the instrument is in good repair, that it has been properly laid, and that the patient has not played any tricks with it. I am now thinking of the manipulation that a hysterical woman may perform. So I repeat high readings of the thermometer, though they may occasion us surprise and even alarm, may be regarded as correct. On the other hand, there may have been some fault in the observation which records a subnormal temperature.

But given an accurate reading of the thermometer which tells you that there has been an abrupt, almost precipitous, fall in the temperature during an attack of typhoid fever one should be on the look out for perforation or hæmorrhage. Severe diarrhœa may also produce a similar fall. The inquiry about the last condition will be quickly answered by the nurse or attendant. Six or more evacuations during, say, 12 hours would attract the remarks of the most careless [illegible]sy to diagnose; and beyond [illegible] of low tension, we would [illegible] upon the exclusion of the other two causes; for you must bear in mind that a hæmorrhage of a severe character even may be occurring in the ileum, in a site possibly seven feet away from the anus, and that it may not discover itself in the evacuations until 24 hours afterwards.

Perforation is not easy to determine, for many of the classical symptoms, such as the pinched, drawn face, acute tenderness, and a thoracic type of respiration, may not be present. But given a sudden fall in the temperature during the third week of fever and having excluded the other possible causes thereof, it behoves us carefully to consider whether perforation may not have taken place, more especially (and this is a point of some importance) if the pulse-rate falls in ratio to the temperature, if its tension becomes suddenly diminished and tends to dicrotism, and if these signs are followed by the phenomena of reaction or rebound to febrility. Then we may assume with some certainty that perforation has occurred and the patient should pass from our care into the hands of the surgeon with as little delay as possible.

Diagnosis of typhoid fever in its earliest stages is notoriously difficult, especially if the attack is a mild one, and most especially in young children. We are accustomed in cases presenting obscurity of diagnosis to fall back on the Grünbaum Widal reaction as an aid to diagnosis. There are in my mind three objections in this method of diagnosis. Firstly, it may fail in its indication even in true cases of enteric fever; secondly, the reaction may be present even though the case should not turn out to be enteric fever; and [illegible]ld always look for this [illegible] The opportunities for [illegible] at hand, at least so [illegible] is concerned, and in addition I strongly deprecate the training of young practitioners to depend on this line of diagnosis. The danger ahead of us is that we may produce a race of medical men who will only make a diagnosis by the help of a syringe, a pipette, and a microscope, and that those excellent characteristics of the older practitioner which have hitherto been the pride of British physicians—the clinical perception and practical knowledge of disease—may be lost in future generations. I would therefore tell you as my experience that one should suspect typhoid fever if there shall have been five days of continued remittent fever with the characteristic daily rise in the temperature curve, even though other symptoms be indefinite.

Treatment demands a few words in conclusion. The diet sheet is the most important factor. During the course of the fever we are accustomed to order beef-tea or other liquid proteid foods freely, but I exclude milk except in small quantities, as it tends to produce, especially if given alone, constipation and large bulky stools. I am also in favour of boiling green vegetables and rice with the animal broth or soup. taking the precaution of having the vegetable matter boiled to a pulp and subsequently strained so as to reject any husks or stringy particles. This bouillon may be given freely and in amount equivalent to half a pound of lean beef per diem. Salt, of course, should be added.

I have not been accustomed to prescribe any drug with a view to disinfect the intestinal canal. I have tried such treatment with salol and other supposed intestinal disinfectants, but so far without success. Nor do I wonder at this, for considering the area of infected bowel and its distance from the stomach it is obvious that any disinfectant which shall hold out any hope of success must be given in doses so large as to constitute in themselves sources of danger and of complications. In addition, after the tenth day and probably earlier, the patient is suffering, not so much from a local lesion or inoculation as from a constitutional disease—a septicæmia, in fact. But there is one method of medication which I have seen most successfully practised by my old friend Dr. John Harley and which we have generally adopted with satisfaction. I refer to the administration of grey powder. My experience is entirely clinical and I am speaking, therefore, only from a clinical point of view. I have found the best results accrue from the prescription of pulvis hydrargyri cum cretâ, two grains three times a day. This is for an adult; a child will require a relatively diminished dose. The effect of this treatment, which was introduced by Dr. Harley before the days of antisepsis, is to secure a regular flow from the bowels; it does not produce diarrhœa and, on the other hand, it obviates constipation. Whether the mercurial preparation has any antiseptic action on the bowel it is difficult to say. Possibly it has and if so its merit in this direction is enhanced by its administration from the earliest days of the fever.

One gentleman has asked, "What constitutes diarrhœa calling for special treatment?" My reply is that anything over six evacuations per diem calls for active measures. I would in this condition advise morphia by the mouth or a starch and opium enema. I am convinced that many of us are somewhat frightened at the use of opium. I am sure that it has saved a goodly number of lives, if only from its sedative action. And I would put it to you tersely, when I say to you "that the indications for opium as a rule outweigh those against it." The presence of albuminuria is its chief danger and indeed its imperative contra-indication.

St. Andrews Graduates' Association.—At a general meeting of the association held on Nov. 5th it was unanimously agreed that the association having fulfilled the objects for which it was instituted should be dissolved and that the balance standing to its credit should be equally divided between the British Medical Benevolent Fund and the Royal Medical Benevolent College, Epsom.

London School of Tropical Medicine.—The Craggs research prize for the best piece of original work don[illegible] the current ye[illegible] or past students of [illegible] been award[illegible] Castellani for his [illegible] to the etiol[illegible] ing sickness. ABSTRACT OF

An Address

ON

THE DAWN AND RISE OF PHYSIOLOGY.

Delivered at the Opening of the Session 1903-04 at the Owens College, Victoria University of Manchester,

By WILLIAM STIRLING, D Sc, M.D. Edin.,
PROFESSOR OF PHYSIOLOGY AND DEAN OF THE MEDICAL FACULTY OF OWENS COLLEGE.

Professor Stirling began his address by entering a plea for the establishment of a lectureship in the history of medicine in the University of Manchester. The early history of physiology, he said, was so interwoven with that of medicine and speculative philosophy that it was impossible to study the one without the other. Recent investigations in Egypt had shown that more than 5000 years ago there were physicians and hospitals established under the Pharaohs. The recent work of Dr. R. Caton of Liverpool had helped to make them more familiar with the ritual and practice carried on in the old Grecian temples, more especially of that of Epidaurus in the Argolian Peninsula which was supposed to have been the birthplace of Asklepios himself. The temples were usually situated in some healthy locality well protected from the prevailing winds, near and yet sufficiently remote from towns, and they were also usually placed near a spring of water. They were at once sanatoriums and medical schools. The physicians, however, were a close corporation and their secrets were transmitted from father to son. Hippocrates, on the contrary, taught openly and was the first to free medicine from the bondage of the sacerdotal ritual. He looked for natural causes for disease. Aristotle might be regarded as the founder of comparative anatomy and comparative physiology. The foundation of the Alexandrian School marked an era in the history of physiology. Under the Ptolomies great encouragement was given both to anatomy and experimental physiology. Alexandria was one of the schools in which Galen studied. As long as the study of human anatomy was practised by dissection of the human body and experiments were made on animals the school maintained its high reputation. With the decline of both came the decline—gradual, but sure—of its fame as a school of medicine, until its final extinction, when the city was captured by the Saracens in 640. Even Cleopatra must not be forgotten, for she induced Mark Antony to transfer the famous library of Pergamos to its rival Alexandria after the burning of the great library of the museum when Cæsar's ships took fire in the harbour. The experimental physiologists in the early days of Alexandria were Herophilus and Erasistratus The former, who flourished about 300 B.C., was the first experimental physiologist. His experiments on animals, however, were not carried out on any systematic plan.

Alexandria was an admirable example of a great commercial city where the sciences flourished and great advances were made in human knowledge. It was a great mistake to suppose that art, science, and literature could not flourish in great commercial centres. All ancient history attested the fact and the recent foundation of new universities in the great centres of industries at the present day was a striking proof to the contrary. The first great scientific societies also were founded in Florence and in London. The next school that had a European fame was that of Salerno. St. Benedict founded the monastery of Monte Cassino in the sixth century, and some time thereafter at Salerno there rose an institution the fame of which lasted for several centuries. At first its teachers were chiefly clerics and there were also many Jews as *magistri*. It lay on the highway of the Crusaders on their way to and from Palestine. By the eleventh century its fame was so great that Duke Robert, second son of William the Conqueror, was stated to have sought the advice of its physicians on his way home from the Holy Land. He had a wound with a fistulous opening in the arm which did not heal. The halo of romance hung round the figure of Sybil, the wife of Robert, who was described as having sucked the wound while her husband was asleep.

It was supposed to be a poisoned arrow wound. Salerno was also distinguished as being the first *schola* to admit to its privileges and honours members of either sex Its practice and its precepts as recorded in the famous "Regimen" seemed conservative to a degree, so that its liberality in the admission of women to its honours was the more remarkable One Constantia Calenda achieved considerable fame Salerno was the first *schola* to insist upon candidates pursuing a definite course of instruction before they obtained their degree The examinations dealt with "verba" rather than "acta" Galen's "Therapeutics" and the first book of Avicenna, the "Aphorisms" of Hippocrates and the "Analytics" of Aristotle were the staple Before obtaining a qualification candidates were required to be 21 years of age They were required to study arts and medicine for seven years A would be surgeon was required to study anatomy for a year The oath was quite unlike the old Hippocratic one Everyone to whatever degree admitted, had to swear "that he would take no fees from the poor nor have any share in the gains of the apothecaries A book was put into his hand, a ring upon his finger, and a crown of laurel upon his head, when he was dismissed with a kiss from the learned doctors"

The rise and development of the earlier universities of Paris, Bologna, and others were then considered The work of Mondinus, the earliest work on anatomy to be illustrated by means of woodblocks, was compared with that of Vesalius The lecture was illustrated by lantern slides copied from the oldest writers on anatomy and physiology

THE ANÆMIAS OF INFANCY[1]

BY CLIVE RIVIERE, M D, M R C P LOND,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL PHYSICIAN TO OUT PATIENTS AT THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST

IN the first two years of life anæmia of a slight grade not infrequently shows itself, mostly in association with rickets, but every now and then cases of more advanced anæmia present themselves and, on account of certain peculiarities with which these cases are associated, they have had a separate label assigned to them and generally go by the name of "anæmia splenica infantum" Whether these cases belong to a class by themselves, and whether they have any claim to be considered a specific blood disease, we will discuss later Let us first review them as they stand

I have tabulated the blood conditions found in the 13 cases which have come under my notice, but space does not permit me to describe their symptoms in detail, I can only give a short *résumé* of those features which they presented in common The clinical picture which they exhibit is closely similar in all the individual cases

A child most often between the ages of nine and 18 months, is brought for advice because it has been gradually losing colour and flesh and has become listless and apathetic Occasionally the enlarged abdomen or even the splenic tumour, is the first thing noticed The onset has been insidious there is always a history of digestive distur[illegible] child is nearly always hand fe[illegible] On examination the child [illegible] with a lemon yellow, waxy skin, it is poorly nourished and its muscles are exceedingly flabby and toneless There is nearly always rickets and that generally of a marked grade The heart is somewhat dilated and there is often a soft systolic murmur at the apex or a hæmic murmur at the base The abdomen is protuberant and tympanitic, the spleen is enlarged and firm, at times reaching nearly to the crista ilii, I have never felt a friction rub over it The liver is large and rather firm, generally reaching one or two fingers' breadth below the costal margin During the course of the illness the temperature shows irregular fluctuations, raised at night and normal or subnormal in the morning though periods of apyrexia may intervene The bowels are opened many times, sometimes seven or eight in the 24 hours, the stools are often greenish and offensive, occasional vomiting is not uncommon A hæmorrhagic condition in my experience is not common, even in fatal cases, only one of my own cases showing such, and that to a slight degree The condition recovers if slight, or if more severe improves under careful treatment, but tends to relapse and the child often lingers a considerable time till a complication, either broncho pneumonia or one of the infective fevers, leads to a fatal issue

This represents an outline of the condition, but within this several interesting points occur and must be separately dealt with First, the condition is distinctly more common among Jewish than other children, perhaps I should qualify this and say Polish Jews, as most of my cases, and indeed most of the East end Jews, belong to this nationality For this reason the disease is the more difficult to study as post mortem examinations are rarely to be obtained and the mothers are often with difficulty persuaded to leave their children for hospital in patient treatment It has been noted by some observers that twins are not infrequently affected, among my own cases neither twins nor, indeed, multiple cases in one family have occurred With regard to the grade of rickets present, this has generally been very marked and more especially has the cranial bossing been out of all proportion to any I have seen elsewhere and was present in marked degree in half my cases This has been before remarked upon by Dr J S Fowler[1] in a paper read before the British Medical Association in 1900 In some of my cases there was also associated with this bossing some craniotabes in the occipital region, and these two conditions occurred apart from any syphilitic taint In only one of my cases was congenital syphilis present Enlarged glands are described by many observers, in only two of my cases were they present and they appeared to exert no influence upon the proportion of lymphocytes in the blood nor on the course of the disease The disease is found in both sexes, in my own cases females preponderated in the ratio of 2 to 1, but it does not seem probable that this is more than an accidental difference Jaundice may occur during the course of the illness Fowler[2] records three instances among his cases In one of my cases it was described in the history I have since seen it in a case not included in my series; in this case it was obstructive in character and probably represents an accidental complication due to the gastro-enteric catarrh When we speak of the gastro enteric catarrh it brings us close, I think, to the etiology of the diseased condition in most of the cases We will therefore postpone its consideration for the present

The Blood

The results of the blood examinations made in my cases are shown in the accompanying table The counts were done with a Thoma Zeiss apparatus, the hæmoglobin was estimated with von Fleischl's instrument, and the differential counts were made from films stained with Ehrlich's triacid stain after fixing with heat

Red Cells —The red cells varied from 1,870 000 to 3,720 000 per cubic millimetre on first examination, the majority being just under 3 000 000 From this they rose to normal under observation in a few cases The colour index was always below the normal which is about 0 8 in infancy, a common figure was 0 5 or 0 6 When improvement took place the red count and the hæmoglobin generally rose together, leaving the colour index unaltered The red cells showed much variation in size very many cells smaller than normal and a few larger being present Less alteration in shape was observable [illegible] generally be seen even wit[illegible] formed a striking [illegible] did not appear to bear any relation to the proportion of red cells present The number falls noticeably as a case improves Of these nucleated red cells a large proportion, from 20 to 40 or 50 per cent., were megaloblasts A few microblasts were also present. The proportion of megaloblasts seemed to bear no relation to the severity of the case, nor does this proportion sensibly decrease or alter when improvement takes place Their numbers are then reduced in the same ratio as the normoblasts

Leucocytes —The number of leucocytes varied between 5000 and 38 000 per cubic millimetre in my cases. All numbers between these two extremes were represented except that they were mostly above the normal 10 000 to 12,000 per

cubic millimetre of healthy children The differential count in these cases presents considerable difficulty. First, among the non granular cells it is very difficult to make any useful division into large and small, as should be done, of course, *if we accept Ehrlich's conclusions as to their quite different* origin. As a matter of fact, in this condition there is every grade between the smallest and the largest, the difficulty being caused by the occurrence of large forms of lymphocyte difficult to separate from the normal large hyaline cell. For this reason I fear the division attempted in my table between them is purely arbitrary and it would perhaps lead to less error had they been grouped together. Another difficulty in some cases is in deciding between small myelocytes and polymorphonuclears, as transitional forms often appear which quite baffle classification. This probably accounts for the rather various myelocyte counts of different observers. The leucocytosis in these cases affects as much the lymphocytes as the polymorphonuclear cells, so that with an increase in absolute numbers they keep their relative proportions or thereabouts. It must be remembered that in infancy the proportion of lymphocytes is greatly in excess of that in adult life and they normally represent at least 50 per cent. of the leucocytes present This may be due to the greater activity of lymphatic structures in infancy and early childhood. The eosinophiles increase or remain normal in this diseased condition as a rule, so that the proportion to the other cells is little changed. Mast cells are found but the detection of these with the triacid stain is so unsatisfactory that I do not claim much accuracy for the percentages assigned to them in my table. Besides these normal cells, in which a general increase occurs, an abnormal visitor, the myelocyte, appears in proportions varying from 1 or 2 to 20 per cent , 4 or 5 per cent. being a common find. Occasionally these cells are found bearing large granules, eosinophilous myelocytes, and in one of my cases as many as 5 3 per cent of these appeared in the blood on one occasion.

And now, are we or are we not dealing with a specific blood disease? The best answer to this is another question. Is there any other form of marked anæmia recognisable in infancy? The answer I should make to that is—No. I have never seen it, have never found a description of such, and see no reason at present to believe in its existence. If cases of marked anæmia of quite another type do exist in the first two years of life they are very rare and must represent some specific blood change, for the common anæmia of infancy is that which progresses, when severe, to the picture of a so called "anæmia splenica infantum." May I here remark that the age of two years which I have fixed as the limit of infancy is, so far as anæmia is concerned, no arbitrary point of time as might at first sight appear, for above this age the infantile anæmias rapidly disappear and examples of the adult anæmias begin to be recorded.

The marked anæmias of obvious causation, such as congenital syphilis, show all the changes claimed by some as peculiar to anæmia splenica infantum. I have at the present time under observation an infant, aged four months, suffering from congenital syphilis of unusually severe type. It presents to observation an interesting double picture: its "obverse" shows a typical severe syphilis with baldness, *café au lait* skin, rash, snuffles, &c ; its "reverse" depicts an anæmia splenica infantum The spleen and the liver are enlarged, as we should expect; examination of the blood shows 1 590,000 red cells per cubic millimetre with 30 per cent. hæmoglobin, and 10,000 white cells per cubic millimetre, the differential count of which is as follows: polymorphonuclears, 30·4 per cent.; small mononuclears, 35 per cent ; large mononuclears, 11 per cent ; eosinophiles, 5 per cent.; *myelocytes, 17 per cent; and eosinophilous myelocytes,* 1 6 per cent. There are 3·2 nucleated red cells to every 100 white cells and of these more than a third are megaloblasts Johann Loos[4] examined 16 cases of anæmia due to congenital syphilis with a similar result. All showed the blood changes characteristic of the so-called "anæmia splenica infantum," and Charles Luzet[5] describes similar changes in cases of anæmia following epidemic diarrhœa.

I would opine, then, that anæmia in infants, when sufficiently severe, always presents the peculiarities seen in these cases, the peculiar appearances noted in the blood and the enlargement of the spleen and the liver; or, to transpose it, that "anæmia splenica infantum" spells merely severe anæmia occurring in infancy, its peculiar characteristics being due to the "infancy" factor rather than the "causation" factor. If this is so we should expect to find all grades of anæmia from the slightest passing insensibly into the more *pronounced condition; and this I hold that we may do*—every grade in the anæmia, every grade in the splenic enlargement, and every grade in the blood peculiarities from one myelocyte and one erythroblast in a differential count up to the large percentage of both found in the more advanced cases The blood changes depend on the age of the child, not on any peculiar reaction to a specific causation. It must be admitted that though every grade may be found it is not so easy in practice to produce cases in intermediate stages, for this reason—either the anæmia clears up rapidly or it rapidly reaches an advanced stage, and once there a vicious circle, presently to be described, is set up and the patient remains for months in the condition described as anæmia splenica infantum. It is difficult to say at what stage the nucleated red cells, myelocytes, &c., appear in the blood, though I believe the anæmia must be fairly advanced before this occurs. Cases occasionally appear in which fairly marked anæmia is found without these blood peculiarities and such cases may be brought forward by some and contrasted with certain cases of so-called anæmia splenica infantum in which the anæmia is only slight but the blood contains nucleated red cells and myelocytes, to prove the specific character of these changes. I think the real explanation is that these first cases have not yet reached the stage at which the blood peculiarities begin and the cases with which they contrast them are anæmias which have been severe but are then recovering, the peculiar blood appearances remaining long after the anæmia has reached a quite mild grade.

And now, having denounced the specific causation of the condition, we are left to grapple with its etiology. I have already claimed indirectly that many causes may produce its peculiarities, being merely those of severe anæmia in infancy, *and it seems probable that the proportions of those various* factors which go to make up these peculiarities vary somewhat according to the causation at work. Indeed, it may be possible at some future time to determine this causation by slight variations in the symptoms present. I have mentioned syphilis as a cause but this, though occasionally present, is certainly not accountable for the bulk of the cases. I have already alluded to the gastro-enteric catarrh accompanying and preceding these cases and this is, in my opinion, the prime cause of severe anæmia in infancy and this cause can generally be traced back one step further—namely, to injudicious feeding Of course the diarrhœa and vomiting will, by those who regard the disease as a specific anæmia, be considered only as part of the disease or as common complications thereof. I admit that once established the anæmia, being a great causative factor of intestinal catarrh, *tends to keep this going. Each reacts upon the other and* this is that "vicious circle" to which I have alluded above; but I hold that in most cases some catarrh can be shown to exist before the anæmia commences. Once this vicious circle is established it is difficult to prevent the downward progress of the case and it is this, I think, which tends to make rather a sharp line of demarcation between these cases of severe anæmia and the slighter grades in infancy; once a certain point is reached recovery is very difficult and they remain a long while *in statu quo*, the ready prey to those complications which so often hurry on the fatal issue. On the other hand, if this point is not reached they tend to recover rapidly and so the stages between are not largely represented clinically.

Among my own cases gastro-intestinal disorders formed an almost constant factor and they generally preceded the disease by a considerable interval Only one of my cases had been breast-fed throughout; the others had been so fed generally for the first few months, just long enough to bridge over the time at which marasmus so commonly occurs. Occasionally they had not been breast-fed at all. In all cases the subsequent feeding had been of a most undesirable nature. Among the Polish Jews, from whom more than half my cases come, breast-feeding is the rule and when this fails, as, fortunately for them, it seldom does, they have even less idea of hand feeding than English mothers in the same class of life. This is sufficient, I think to account for the excessive proportion of Polish Jews among my cases, but to it may be added the fact that slight grades of anæmia also are very common among these children and seem to be very readily produced In the first few months of life gastro-intestinal catarrh leads to marked wasting, but in the later months of the first year, when the disease under consideration tends to appear, marked wasting less commonly shows itself than does rickets with poor nutrition and flabby muscles, so that these anæmias may be taken to correspond in later months to the marasmus of early infancy. In the early months the injured intestinal glands are unable to take up nourishment and the child starves; in the later months they have learned their function in this respect and take up not only nourishment but in addition toxins formed from the altered food substances. That rickets can be a cause of anæmia, or, indeed, of anything other than mechanical deformities, I cannot persuade myself to believe, being itself but a series of symptoms—a reaction of certain tissues to some cause or causes underlying it. That one of these causes—namely, gastro-enteric catarrh—may, at the same time that it causes rickets, also lead to marked anæmia, and that an anæmia of such a kind as has been described under the title "anæmia splenica infantum," I believe and hold. The rickets, in my opinion, in these cases runs parallel to the anæmia. The fact that the anæmia may occur without rickets and that rickets is not necessarily associated with marked anæmia proves that neither depends on the other, nor can their causation be altogether identical.

---

[4] Johann Loos: Wiener Klinische Wochenschrift, 1892 No. 20.
[5] Luzet: Revue des Malades d'Enfance, 1891, p. 199.

And now, how does the intestinal catarrh act as a systemic poison? Intestinal toxins have been conjured up to explain so many varying conditions, and their appearance is so trite and convenient as a causative agent that it is with some shame and with many apologies that I drag them forward. If I could give you a table of their analysis—if I could show them on a plate—it would be very gratifying to me and very edifying to the Fellows of this society; but although this may not be done yet we cannot afford to ignore their formation. In cases of acute gastro-enteritis in infants no one would have the hardihood to deny an absorption of toxins from the intestinal canal; when such a condition of toxin formation and absorption goes on insidiously over a long period of time a different train of symptoms will be produced, a slow poisoning of the tissues, leading—why not?—to marked rickets and severe anæmia, the so-called anæmia splenica infantum. The organisms causing acute summer diarrhœa have yet to be definitely decided upon. Shiga's bacillus[6] and various members of the coli group have been claimed as such, and it seems probable that more than one organism, given favourable conditions, is capable of causing the symptoms of this disease. Similarly, in chronic catarrh, set up in the first place by unsuitable food, it is probable that the growth of organisms, differing, perhaps, according to the food supplied, may serve to keep it going, and that the products formed by their growth in these food substances, being absorbed, will cause a progressive poisoning of the human host. Once a suitable culture medium is prepared for them in the intestine there is no lack of organisms, either already present or introduced in food through the disordered stomach, to flourish upon it. Another possible source of poisoning remains to be mentioned—namely, toxins formed as the by-products of disordered digestion in these cases. And now, though we may not believe that we are dealing in anæmia splenica infantum with a primary blood disease, though we hold that those peculiar cells the occurrence of which is described above are readily called forth into the blood in infancy, still there must be a *modus operandi* under which they appear; they are not there without cause, and since we believe that an intestinal toxæmia is that commonly at work it is interesting to attempt on those grounds some explanation of the changes observed. The views of Ehrlich as to the origin and destination of the blood cells seem to be those most widely accepted. It will therefore be convenient to base a working hypothesis on those views.

We have supposed a toxin formed in the intestinal tract either by the action of micro-organisms on the undigested food-stuffs or as a by-product of disordered digestion. This, by its local action, will cause diarrhœa and vomiting and by the stimulation of intestinal lymphoid tissue will wash into the blood that increase of lymphocytes which commonly accompanies a gastro-intestinal catarrh in children. The poison circulating in the blood stimulates the bone marrow; by an active chemiotactic reaction an increased supply of polymorphonuclears and eosinophiles takes place, causing a leucocytosis, perhaps with a view to helping in the formation of antibodies to the poisons in the blood; but after a time this leucocytosis fails relatively, and to keep up the demand only partially formed granular cells, the myelocytes, antecedents of the polymorphonuclears, appear in the blood. If this failure of leucocytosis is a fact, it should not be possible to cause a polymorphonuclear leucocytosis in one of these cases. I am not sure about this point. One of my own cases in an attack of pneumonia showed an increase of leucocytes generally but no relative increase (even a slight decrease) in polymorphonuclears. The leucocytosis having failed to overcome the poison, and the same being still formed, a destruction of red cells takes place, the spleen being enlarged partly to dispose of the refuse of these and the dying leucocytes.

That an increased destruction takes place seems to be supported by the following facts: 1. The presence of erythroblasts in the blood, suggesting an attempt on the part of the marrow to keep up the supply. The megaloblasts present probably depend merely on the age of the patient, these being normally present in the marrow of infants. 2. The altered proportions between the young cells (large mononuclears and myelocytes) and the old cells (the polymorphonuclears) seem to point to increased destruction of the latter. 3. The alterations in size and shape of the erythrocytes may be due to a degeneration preceding their death. It might be argued, on the other hand, that these changes may be brought about by a poisoning of the blood-forming organs resulting in their inability to supply adult cells to the blood and so allowing immature forms to enter the circulation. If the increased destruction were great it might cause some increase in the iron content of the organs, especially of the liver if it occurred in the portal circulation, as one might expect in an intestinal toxæmia. If the destruction were in the general circulation, on the other hand, there might be no demonstrable increase of iron content in the abdominal viscera. In the only fatal case I have had in which a necropsy was permitted I got Dr. W. H. Hurtley to estimate the iron in the liver, the spleen, and the kidneys. He employed two methods for comparison and found in the spleen 0·01585 per cent, or 0·01818 per cent.; in the liver 0·01527 per cent., or 0·01566 per cent.; and in the kidneys 0·022 per cent., or 0·00287 per cent., or 0·0036 per cent. of iron as the result of three experiments with the two different methods. Dr. William Hunter[7] among 20 collected analyses of normal organs found the iron content for the adult an average of 0 078 per cent. for the liver and 0·171 per cent. for the spleen. The percentages in the child seem to correspond closely with these among the few analyses in infants I have been able to find. We see, therefore, that the percentages in my case of anæmia were low and, even allowing for an increased bulk of liver and spleen, do not point to any excess of iron in these organs such as occurs in the liver in pernicious anæmia Does this mean that blood destruction plays no important part in this disease? I think not.

Let us glance at the condition in pernicious anæmia. In that disease Dr. Hunter has clearly shown that the blood destruction occurs in the portal circulation and the poison, intestinal in origin, as also the products of its action, the iron, &c., never get beyond this point, but are dealt with by the liver before they reach the general circulation. But we have advanced the theory of an intestinal toxæmia in these anæmias of infancy also; how does it differ from that described above? Obviously in this, that in them the poison reaches the general circulation. The myelocytes and increased polymorphonuclears clearly point to a direct action through the blood stream on the bone marrow. We must thus suppose that the toxin, though entering the portal circulation, as in the case of pernicious anæmia, is not destroyed by the liver, but finds its way into the blood stream wholly or in part and there exerts its action on systemic structures. The blood destruction if such exists, occurs in the general blood stream and its products are scattered broadcast instead of being seized and stored in the liver, as in pernicious anæmia. On the other hand, it seems quite likely that a deficient formation as well as a blood destruction is at work in this condition. That the blood-forming organs, and especially the bone marrow, are disturbed in this affection we have evidence in the unusual distribution of the leucocytes, and the relative deficiency of the hæmoglobin content of the red cells seems to point to the same and suggests a likeness to chlorosis in which a deficient production in all probability takes place, whether a dilution of the plasma is also present or not.

Three severe blood conditions in infancy have received recognition at various times in the past—anæmia splenica infantum, *anæmia splenica pseudo leukæmica of von Jaksch*, and leukæmia The first we have considered; when we come to a consideration of the other two we are met at the outset by a *great difficulty—namely, the very imperfect* blood examination made on the cases described

Let us take leukæmia first, and by this term we mean spleno myelogenic *leukæmia, for it is this variety that the* infantile anæmias resemble What grounds are there for [illegible] it [illegible] number of cases have been described, but in almost all on quite insufficient evidence, and apart from one or two cases, in which the matter was more thoroughly proved by post mortem examination, one would be strongly inclined to discredit the occurrence of the disease at all in the first two *years of life*

The most complete case I can find is one described by von Jaksch[8] in 1889 In this case, that of an infant, 14 months old, there was a progressive increase of leucocytes up to 192,000 per cubic millimetre at the time of death At the necropsy the organs showed typical leukæmic changes and these were confirmed by microscopic examination No differential count was made Then comes a case recorded by Stilling,[9] that of an infant aged 12 months, in which the organs showed definite leukæmic changes on the post mortem table No blood examination was made A third case is that recorded by Hochsinger and Schiff[10] in an infant aged eight months, it developed tumours of the skin, which microscopically showed a typical leukæmic infiltration It appeared to be a mixed splenic and lymphatic leukæmia, but no post mortem examination was obtained Middleton's[11] case, that of an infant aged 16 months, showed a leucocyte count of 370 000 per cubic millimetre (no differential count being made), but post mortem no naked eye leukæmic changes in the organs were found though microscopically the capillaries were found stuffed with leucocytes representing perhaps, an early leukæmic infiltration Dr H D Rolleston and Dr A O Latham[12] have described the necropsy on a child 18 months old whose organs showed a similar change, but they seemed loth to consider it a case of leukæmia and on other grounds a diagnosis of lymphadenoma was made In all the other cases I have been able to trace there has been some omission which has weakened their claim to be considered instances of this disease In Morse's[13] case, so often quoted no post mortem examination was made and there is, to my mind, nothing about the condition of the blood which clearly separates it from other cases of grave anæmia in infants The myelocytes, it is true, rose to 21 4 per cent, but one of my own cases showed a myelocyte count of 21 5 per cent and a larger eosinophile count than his Perhaps I ought to have called this a case of leukæmia but I could see no clear reason for doing so in the absence of a post mortem examination Another of my cases which has improved considerably under treatment showed 16 per cent of myelocytes These represent all the cases I can find in infants under two years of age in which a claim for leukæmia was made In children between three and four years old, an age somewhat beyond the limits of those anæmias with which this paper deals, a few cases also of leukæmia, both spleno [illegible] re and some [illegible] which must [illegible] he year 1890 von Jaksch[14] described some cases which he burdened with the somewhat cumbersome title of "anæmia infantum pseudo leukæmica, and these he separated from leukæmia on the one hand and from splenic anæmia of infants on the other They were cases in which a leucocytosis occurred out of proportion, he thought to cases of so called "splenic anæmia," but in which the post-mortem lesions of leukæmia were missing

To recapitulate shortly the changes found in our cases of "splenic anæmia"—we have considerable anæmia, enlargement *of the spleen* and the liver, and generally, advanced rickets The blood shows a low red count with a still lower colour index The leucocytes are moderately increased and a *differential count among them shows myelocytes* in fair numbers and many nucleated red cells, both normoblasts and megaloblasts The cells normally present keep near the normal proportions of infancy

Now how do these cases differ from those described by von Jaksch as anæmia splenica pseudo leukæmica? Von Jaksch himself sums up the difference on three lines (1) the smaller leucocyte count, (2) the absence of progressive increase of leucocytes, and (3) the presence of marked rickets. The leucocyte counts in his three cases at their highest were respectively 54,000, 114,000, and 36,000 per cubic millimetre The latter two of these cases recovered and the count fell in one case from 114,000 to 10 000 per cubic *millimetre in three weeks and in the other case from* 36 000 to 12 500 per cubic millimetre in six weeks In face of this fall and of the way in which the interval between the high and low counts is bridged [illegible] surely the large leucocyte count [illegible] as a distinction between these ca[illegible] cases described above If any [illegible] should be very glad to learn at what number of leucocytes per cubic millimetre they would place the line of demarcation between them As for the progressive increase of *leucocytes, this may occur in fatal cases of all sorts* and is not peculiar to von Jaksch's cases Death depends upon persistence of the morbid condition, except when due to complications, and the leucocytosis runs parallel with this

With regard to rickets, no very definite conclusion can be drawn All my patients except one had rickets, most of them marked rickets, and I am disposed to regard the condition as a result of the same cause that produces the anæmia rather than as itself contributory in any way to the causation of the disease The case in which there was no rickets differed in no *respect from the other cases* either in history or symptoms, moreover, in one of the patients in von Jaksch's three cases had rickets is mentioned, so that this disease, since it is not always present in the one condition and may be present in marked form in the other, can be taken neither to explain the one nor its absence to distinguish the other Morse affirms the presence of rickets also in nearly all authentic cases of leukæmia which has some bearing on what follows

It may be accepted, I think, that the difference between the cases described by von Jaksch as "anæmia splenica pseudo leukæmica' and the cases of anæmia with enlarged spleen described above is one of degree only and not of kind

And now the question arises In what respect, if at all, do these cases of anæmia splenica differ from those of leukæmia mentioned above?

First we do not find that the blood condition in these cases of leukæmia quite corresponds with what we should expect to find if we reason from the grounds of the same disease in the adult In the adult we have an average of about 300 000 white cells per cubic millimetre, and of these about 30 per cent are myelocytes, moreover, there is a definite *increase of eosinophiles and mast cells Now in* healthy infants the leucocyte count is somewhat higher than in adult life and a leucocytosis is admittedly very readily set up and yet in these cases of leukæmia what do we find? Only 192 000 per cubic millimetre in von Jaksch's case at the highest and only 48 000 in Morse's case, whereas in older children quoted by Cassel and Baginsky at eight and nine years *respectively there is no such failure in this respect*, the leucocytes being 500 000 and 986 000 per cubic millimetre respectively This alone, in the absence of a post mortem examination throws considerable doubt on Morse's case and the very moderate myelocyte count of 21 4 per cent. among these seems to confirm it. In Middleton's case on the other hand, there were 370 000 leucocytes per cubic millimetre, a much more respectable number In the other cases, unfortunately, the leucocytes were not counted—merely recorded as increased More unfortunately still we miss the advantage of a differential count in all but Morse's doubtful case, for seeing the readiness with which myelocytes appear in the blood of infants (in diphtheria, &c) and also the case with which an eosinophilia is in them set up we should expect to see a very striking percentage of these two classes of cell in leukæmia. In Morse's case, as we have seen, there are only 21·4 per cent. myelocytes, a number which may be reached in fatal cases of anæmia splenica infantum and only 0 6 per cent. of eosinophiles, which represents no definite increase at all in such a comparatively small leucocyte count. In Rolleston's doubtful case the myelocytes numbered 20 per cent. and the eosinophiles 1·6 per cent., but we do not know what absolute increase this represents as no blood count was made. In neither Middleton's case nor in von Jaksch's case was a differential count made but the latter informs us that there was no increase of eosinophiles. So that in those cases recognised as leukæmia in which a blood examination was made we find that the blood does not bear the characters we should have expected under the modifying influence of infancy.

[illegible] Ss 400, 414

Once more where do these cases of leukæmia differ from cases of splenic anæmia and von Jaksch's anæmia already described and where does the line of demarcation come, if such exist? That their appearance is strikingly similar is illustrated by the difficulty the older observers had in separating the two conditions; indeed, many of the splenic anæmias were described under the heading of leukæmia. Von Jaksch considers that the conditions can be separated clinically on several grounds.

1. He says that the liver is more enlarged in leukæmia than in splenic anæmia. What do we find on examining the facts? In von Jaksch's own case of leukæmia the liver was only just palpable below the ribs and after death it weighed 500 grammes, with a spleen of 430 grammes; in my own fatal case of splenic anæmia, in which a post-mortem examination was obtained, the age of the child was the same; the liver weighed 405 grammes, compared to a spleen of only 112 grammes—i.e., in my case of splenic anæmia the liver weighed nearly as much absolutely and relatively to the spleen much more than in his case of leukæmia. In Hochsinger and Schiff's case the liver was larger, reaching below the umbilicus; in Middleton's case the liver is definitely mentioned as *not* enlarged; in Stilling's case it is said to be rather large but no weights are supplied; in Morse's case it came two fingers' breadth below the costal margin, so that the enlargement of the liver as a point of diagnostic importance between the two diseases appears to be of very little worth.

2. The second point von Jaksch states is that the eosinophiles are increased in leukæmia but diminished or absent in anæmia splenica. This increase in leukæmia is certainly what we should expect, but we have already seen that in leukæmia infantum they seem to be *not* necessarily increased, and in von Jaksch's own case he definitely states that no increase occurred. On the other hand, there is a fair percentage (generally about 1 per cent.) working out to a slight real increase, or at any rate no diminution, in the other disease as illustrated by my own cases.

3. His third point is that anæmia is a more important feature among the cases of so-called anæmia splenica infantum than among cases of leukæmia in infants, but I do not think that this distinction is of much value. One of my patients died without definite complications with a blood count of 3,750 000 red cells per cubic millimetre and 23 per cent. hæmoglobin, another with 3,180,000 red cells per cubic millimetre and 30 per cent. hæmoglobin; while in von Jaksch's own case of leukæmia the red cells fell to 2,310,000 per cubic millimetre before death, in Middleton's case they were 3,300 000 per cubic millimetre, and in Morse's supposed case they were 2,900,000 per cubic millimetre, so that there is really nothing to be said between the grades of anæmia in the two conditions.

And now comes the only distinction which appears of importance—the only line, as far as I can perceive, which can be drawn between the two diseases, and it is this: in leukæmia the organs are found after death to be infiltrated with leucocytes; in anæmia splenica, on the other hand, they are not. Can this barrier be passed? Can we conceive that perhaps this, too, only represents a grade of disease, that anæmia splenica infantum is merely leukæmia which has never reached the stage at which infiltration of the organs occurs and that leukæmia merely represents an acute and advanced phase of the less serious-looking disease? I would advance the suggestion that we can. I cannot help thinking that cases will be found bridging over the gap between severe anæmia and leukæmia of infants—cases in which an infiltration of the organs is beginning to take place at the time of death—in which, though no alteration is observed in the organs by the unassisted eye, yet the microscope reveals the early beginnings of that change which in a more advanced grade causes the distinctive lesions of leukæmia. Are not Middleton's and Rolleston's cases illustrations of this commencing infiltration?

If we accept these contentions which I have laid before you to what do we commit ourselves? 1. That *severe* anæmia in infants commonly presents the picture of so-called anæmia splenica infantum or of anæmia splenica pseudo-leukæmica and that the causation of such severe anæmia is generally an absorption of intestinal toxins. 2. That if the condition is *more* severe, probably from a somewhat more acute poisoning, the picture of leukæmia infantum is produced—i.e., that leukæmia in infants is nothing more than the most advanced example of a morbid condition represented in its pre-leukæmic stages by the conditions known as anæmia splenica infantum and anæmia splenica pseudo-leukæmica of von Jaksch.

So far it looks easy, but other issues must be reconciled. Some may object that leukæmia is a very fatal disease, whereas recovery takes place from the slighter cases of anæmia splenica. This should not disturb us. Children react very differently to various diseases than do adults, and because leukæmia runs a well-recognised course and is almost certainly fatal in later life there is no reason why the same should obtain in infancy. The mortality, moreover, be it noted, is by no means low among marked cases of splenic anæmia (so-called). More than half of the patients among my own cases are already dead and others are likely to follow. I can only record two recoveries as yet among my 13 cases.

The next point we are met with is the comparative frequency of leukæmia, or rather its antecedent anæmias, in infancy, and this is what we should expect if its causation is not specific. It represents the natural reaction of the blood-forming organs in infancy to various poisons, and in this respect may be compared to broncho-pneumonia which is also commoner in infancy than in adult life and is the result in the infantile lung of the inroad of many different organisms.

And now we have broken the ice of the next somewhat startling conclusion to which our arguments have necessarily led us—namely, that leukæmia in infancy is not a specific disease. Something needs to be said on this head. Naturally the slighter causes of anæmia in infants would not be expected to lead to a leukæmic condition; it is to the serious anæmias only that it is closely related. These serious cases, I would suggest, are always intestinal in origin and if the poisoning is severe enough a leukæmia may be the result. Obviously there is something peculiar about this poison; it must be produced continuously over a long period of time and it must be capable of escaping the vigilance of the liver either directly or by entering the blood through the lymph stream. In health the liver has the power of absorbing poisons carried to it in the portal circulation and of returning them to the intestine in the bile. The poison of pernicious anæmia seems to be caught in this way and exerts its influence on the blood in the portal circulation only.

On the other hand, it seems probable that many poisons are capable of evading this action of the liver, as is exemplified by cases of acute gastro enteritis in infants. Here the symptoms of a general toxæmia are rapidly established and it seems certain that similar symptoms may be caused by the action of more than one organism in the intestine. If this is so in cases of acute poisoning I think we are bound to admit that in the chronic poisoning which leads to anæmia or leukæmia no specific organism need be pressed into service but many may be capable of causing it. This contention becomes more difficult when we turn to leukæmia in the adult. Here we see none of those slighter forms, none of those pre-leukæmic stages from which recovery may take place; it is either "neck or nothing." This fact makes it evident that the causation in adults is considerably narrowed, that but few organisms can form poisons capable of originating the disease, and that a peculiar environment is necessary for their growth. The disease is rare. Moreover the blood-state is for the adult, though not for the infant, something quite peculiar and specific; it is no less than a return to the condition of an infantile anæmia. How can this be explained? We have dismissed the specific character of the blood changes in infantile anæmia as untenable, though we have nevertheless claimed that an intestinal toxæmia is the common cause of the condition—of the severe cases and leukæmia probably the only cause. But if the blood changes are not specific and depend merely on the "infancy" factor, how can these same changes be brought about at the call of a diseased condition in adult life?

For an explanation of this let us turn for illustration to another disease of infancy the peculiarities of which are exhibited less frequently in adult life—namely, broncho-pneumonia. It must be understood that I use broncho-pneumonia as a convenient illustration only and do not claim it as a parallel to the disease I am discussing. I am well aware that the occurrence of broncho-pneumonia in infancy depends largely on the physical peculiarities of the infantile lung and is therefore not directly comparable to a tissue reaction such as that we are discussing. At the same time the illustration may be closer than at first sight appears, since the prevalence of the "leukæmic" anæmias in infancy may also depend to some extent on a physical factor—the infantile intestine in place of the infantile lung.

Acute broncho-pneumonia is essentially a disease of infancy and can be caused by any of several organisms—pneumococcus, streptococcus, staphylococcus, diphtheria bacillus, influenza bacillus, &c. The pneumococcus, as we know, is by far the commonest cause. It is often present in the throat in health and only awaits certain conditions favourable to its growth to set up the disease. To adults the pneumococcus is a much less formidable enemy and if it does gain an entry causes, not broncho-pneumonia as in infancy, but a somewhat different morbid condition—namely, croupous pneumonia. But broncho-pneumonia also occasionally occurs in adult life, though it is a disease of infancy. The pneumococcus does not cause it but the influenza bacillus, a very rare cause in infancy, in adult life readily sets up a typical broncho-pneumonia.

Let us apply the above facts to illustrate what may occur in leukæmia. The leukæmia of adults though it displays certain noticeable differences, bears a close resemblance in its blood changes to leukæmia and the severe anæmias of infancy and may be considered to be, I think, a return to an infantile condition. This condition of blood is comparatively common in infancy, representing the natural reaction at this early age, and like broncho-pneumonia might be caused by the poisons of many different organisms (intestinal), of which probably one (like the pneumococcus in broncho-pneumonia) is more commonly active than others. After infancy is passed the tendency to this blood reaction is passed also, but still the condition may occasionally be set up in adult life. Like broncho-pneumonia fewer organisms (possibly only one) may, developing in the intestine, be able to cause it in later life and that perhaps a different one (compare adult influenzal broncho-pneumonia) from that which commonly sets it going in infancy (compare pneumococcal broncho pneumonia). Thus, though leukæmia (including the pre-leukæmia anæmias), being only the natural reaction to various poisons, may not be considered specific in infancy, yet in adult life it may become specific in that the blood changes are quite peculiar when compared with other adult blood conditions and its causation is so narrowed down as to be practically solitary.

I would, then, sum up my conclusions as follows:—

1. That anæmia from any cause in infancy if severe enough gives rise to the peculiar symptoms grouped under the headings "anæmia splenica infantum" and "anæmia splenica pseudo-leukæmica" of von Jaksch.

2. That, consequently, these are not specific blood diseases but owe their peculiarities merely to the "infancy factor" and that they represent merely different stages of the same condition.

3. That the common cause of severe anæmia in infants is gastro-intestinal catarrh, leading to the absorption of toxins either from the growth of micro-organisms or possibly from the formation of poisonous by-products of digestion.

4. That leukæmia of infants is not a separate disease, but merely a still more advanced stage of this anæmia—that is, that the difference between them is one of degree and not of kind.

5. That leukæmia of adults is a return to the condition of an infantile anæmia and that, being rare, its causation is probably so narrowed down as to be practically specific.

In conclusion I would like to express my thanks to my colleagues at the East London Hospital for Children for their kindness in supplying me with opportunities for studying those cases which came under their care.

I feel also that an apology may be expected from me by you, gentlemen, for having placed before you so much theory to-night and so few new facts. If it is expected I offer it in all heartiness; at the same time I cannot but feel that an attempt, however inadequate, to reason from facts already accumulated and to build up a working hypothesis upon them should have as much claim to your consideration as the mere accumulation of those facts themselves. If we could believe that leukæmia in infancy merely represents a severe grade of so called splenic anæmia and that leukæmia in adults is a return to a condition of infantile anæmia it might, I venture to think, bring us a step nearer to the comprehension of this interesting disease.

Devonshire street, W.

A CASE OF MULTIPLE LIVER ABSCESS.

BY ANDREW BALFOUR, M.D., B.Sc., M.R.C.P. EDIN., D.P.H. CANTAB.,
DIRECTOR, WELLCOME RESEARCH LABORATORIES, GORDON COLLEGE, KHARTOUM

THE following case of multiple liver abscess appears to me worthy of being placed on record for the following reasons: 1. The comparative rarity of the site of the larger abscess and the somewhat infrequent nature of the smaller. 2. The apparent absence of dysentery as a forerunner. This is seemingly no uncommon occurrence in the Sudan where I believe that in cases of hepatic abscess a history of dysentery is rarely obtainable. 3 The possibility that the affection of the liver was antecedent to a dysenteric attack which was cut short by the fatal issue of the case. 4. The great rapidity of the course of the disease and the absence of symptoms pointing to the full gravity of the condition. 5. That a fatal result followed exploratory puncture, a very rare event to judge by reports given in the literature of the subject. 6. There was some question as to the real nature of the pathological condition.

In the month of June, 1903 I was called in consultation to see a medical officer of the Egyptian army, a surgeon of repute with an extensive knowledge of tropical surgery, a point of importance in the case, as will be seen. He had been ailing for three days and the facts to be noted in the history given me were as follows. The patient was a strongly built man, 29 years of age, though he looked older, of dark complexion, a very typical Celt, extremely temperate, accustomed to plenty of exercise, and with a record of four years' medical work in Egypt and the Sudan. He had never suffered from malaria, enteric fever, dysentery, or, indeed, any serious malady. At a later date I learned that a year previously his blood had been examined for the hæmamœba malariæ with a negative result, but that eosinophilia was present at that time. He had never, however, had any symptoms pointing to an infection by metazoal parasites. He was always most careful to avoid taking chill, constantly wearing a cummerbund and possibly carrying his precautions almost too far, as he rather burdened himself with clothing. Immediately prior to his illness he had been overworked. In addition to his ordinary duties, which were sufficiently arduous, he had been studying hard for an Arabic examination and in consequence had been unable to take his accustomed recreation in the shape of golf or riding. For some little time he had been looking fagged and it is worthy of note that a few days before he became really unwell he had been attending a case of slight dysenteric diarrhœa in the house in which he himself lived and slept. At the time he fell ill a case of bad enteric fever was also under his charge. It should also be mentioned that just prior to his illness his nose had been cauterised with chromic acid for a [illegible] condition of the mucous membrane. On the [illegible] h he first complained he had [illegible] very cheerful and lively—in fact, he seemed to be in excellent spirits. He partook of a good deal of iced, non-alcoholic drink and stated afterwards that he felt it very cold on the stomach and feared it might have given him a chill. The following morning he felt seedy, complained of nausea, flatulence, and some pain in the epigastrium. He had no diarrhœa but his temperature was about 100° F. He was seen by his brother officer, Captain Sterling, and regarded as a case of gastric catarrh, nothing abnormal being found on physical examination. He was dieted and given a mild aperient, but passed a restless night and next day was no better. He suffered from pain in the back and abdomen, a feeling of general discomfort, and his temperature still remained somewhat elevated, tending to rise towards evening. So he continued for another day, obtaining some relief from hot fomentations to the epigastrium and at his own request being given small doses of opium which secured him some rest. He would not keep to his bed but remained in his room and felt unfit for any work. His bowels were moved and nothing special was noticed about the stool—no trace of blood or mucus, no loss of colour, and no offensive odour.

I saw him for the first time on the morning of the fourth day of his illness (June 10th) and found him with a temperature of 101°, not looking very ill but rather distressed and anxious and much bothered with belching and the heat. On inquiry I elicited the fact that he had a feeling of discomfort about the right shoulder-blade, which, however, was less than it had been. His complexion was rather muddy, his conjunctivæ were not jaundiced, his tongue was fairly clean —a "milk tongue"—and not flabby, his abdomen was somewhat distended, and there was distinct tenderness on pressure over the epigastric region but no sense of resistance to the palpating hand. There were no enlargement of the liver or spleen, no hepatic friction, and no dilatation of the stomach. Indeed, all that a careful examination revealed was a certain harshness of the breath sounds over the base of the right lung, which had been detected by Captain Sterling on the previous day. There were no accompaniments. The urine was free from blood, pus, or albumin, but on standing deposited numerous crystals of urate of ammonium. No leucin or tyrosin was found. He had become a little costive but was given a small dose of calomel followed by Carlsbad salts and his stools in no way differed from the normal. It was felt that he was suffering either from a gastritis or a hepatitis or both combined, though at first the question of a commencing attack of enteric fever was considered. This was soon discounted by the state of the tongue, the general condition, the absence of splenic enlargement, and the prominence assumed by the liver symptoms. The patient evidently feared the formation of a liver abscess for he at once expressed a hope that such might not develop and the fear of it soon dominated his mind, though otherwise he was cheery and very patient and hopeful.

It was proposed to substitute an ice-bag for the hot fomentations but the patient preferred the latter and the application of mustard leaves over the painful area. Leeches were not available or they would have been employed. He was put upon an alkaline treatment, was given a carminative mixture and anti-curdling powders, and kept strictly to a milk diet. For two days there was little change in his condition and what there was tended to show improvement. His nausea and pain diminished. The feeling of discomfort in the shoulder disappeared, his flatulence became less marked, his appetite improved, and save for persistent insomnia he did not feel very unwell. The sleeplessness greatly troubled him and he insisted each night on getting a little opium. Sulphonal was tried but did not agree with him and increased his restlessness. Bromide had no effect. He was examined twice daily but no change could be detected, the lower edge of the liver being at the costal margin in the nipple line, the upper border remaining unchanged, while there were no increase of tenderness and no feeling of resistance in the epigastrium nor any hepatic increase there. A nurse was in attendance and he derived much comfort from repeated spongings. Thereafter, however, and synchronous with a commencing pallor of the stools, an enlargement of the left lobe of the liver was detected. The increase had come on very rapidly and caused a distinct fulness in the epigastrium while there was resistance to the palpating hand. A certain amount of cutaneous œdema due to the counter irritation added to the appearance of fulness. The question of the occurrence of abscess had all along been kept in mind and now a surgeon, Dr. J. B Christopherson from Omdurman, was at once summoned. He concurred in the opinion that pus had probably formed in the liver and it was decided to make an exploratory puncture and to proceed if necessary to evacuate the abscess. The patient, however, though his general condition was very good—he had been able to take and to relish some chicken-tea and jelly—was anxious-minded. He had himself noticed the swelling in the epigastrium and fully appreciated its significance. For this and other reasons, one of which was that it was hoped he might get a good night's rest before anything was done, it was resolved to defer further action till the following morning. The patient passed a very fair night and on the morning of the 15th stated that he was feeling much better. His temperature had fallen to 100° and his pulse to 92 and he felt so well that he was able to write two important letters There was a further increase in the size of the left hepatic lobe but there were less tenderness on palpation and no pain.

Although the patient expressed perfect confidence in his surgeon and gave permission for anything to be done which might be considered necessary he was very nervous and his pulse was not so strong as could have been desired. He was accordingly given some brandy and about 11 A M. was ready for operation. Captain Sterling administered chloroform which the patient took well and as soon as he was fully under the influence of the anæsthetic Dr. Christopherson inserted a hollow needle attached to a syringe at a spot opposite the ninth left costal cartilage and about one and a half inches internal to it. The point of the needle was directed slightly upwards and inwards. At first a little blood-stained serum was obtained and then a small quantity of thick greenish pus. Some of this, which must have been from the wall of the abscess cavity, was afterwards examined by me and the amœba dysenterica was found to be present No other organism was encountered. I may add here that the blood was also examined and no malarial parasites were found. A differential leucocyte count was not performed, which in the light of the fact that the patient's blood had previously shown eosinophilia is much to be regretted. The quantity of pus obtained was so small that Dr. Christopherson thought it advisable to make two other punctures close to the first. On one occasion a little pus came away; the other puncture only yielded blood-stained serum. It was clear that an abscess was present but it was thought well to make a fourth puncture about the middle line in the epigastric region, directing the needle a little downwards and to the left to discover if the abscess cavity approached nearer the surface there than it appeared to do in the first spot examined. Blood alone was obtained.

Everything was in readiness for the necessary evacuation of the pus but the patient's condition suddenly became extremely alarming. His pulse at the wrist almost vanished, his respirations were laboured, and he began to get cold. There were no loss of colour in the lips and no dilatation of the pupils and the condition appeared to be solely one of nerve shock. This was further evidenced by a severe trismus of the lower jaw setting in. All thought of further operation had to be abandoned for the time being and every effort directed to improving the general condition, fortunately with good results. Ether and brandy were given subcutaneously, heat in the form of hot bricks was applied to the feet, the jaws were forcibly separated, and in a short time the patient had revived. The distressed mental condition was evidenced by his anxious inquiries regarding the operation before he was well out of the chloroform, as he kept urging us to make haste and to finish. Once conscious he rapidly picked up and about 12 45 P.M. when I left him he was much better, his pulse having regained tension while he was comfortable and free from pain. It was unanimously agreed, however, that nothing further of an operative kind could be attempted till there was a greater improvement in the general condition.

Captain Sterling, Dr. Christopherson, and the nurse remained in attendance upon him but at 3 P.M. I was hastily summoned and found that he had again collapsed; he was sighing heavily, tossing his arms about, his pulse was almost imperceptible, and his body was bathed in cold perspiration. It was feared that there might be hæmorrhage into the peritoneal cavity but his lips were of a good colour and there was no abdominal distension. He was perfectly conscious and said that he had no pain but his voice could not be raised above a whisper. Regarding the condition as a recurrence of nerve shock, a diagnosis fully borne out by the absence of any evidence of hæmorrhage post mortem, we treated it by raising the foot of the bed, administering champagne and strychnine, giving hot coffee by the mouth and hot water as a rectal injection, applying a hot bag and a mustard leaf to the præcordium—in short, stimulating as much as possible. Transfusion apparatus was got ready but was not required, for he rallied rapidly and was soon able to state that he felt much better, though as before he expressed fear regarding the hepatic condition. He continued to improve towards evening, became quiet and restful, and took nourishment freely. Towards night he began to wander a little but when I last saw him at 9.30 on the evening of June 15th his condition was such as to give one hope that the operation might yet be successfully carried out. His temperature, however, had begun to rise. Unfortunately, the hope was not realised, for about 11 P.M. he began to get excited, a reaction set in, his temperature ran up to 106°, and though his two medical attendants did all in their power to save him he collapsed and died quietly about 1.30 A.M.

Post-mortem examination.—Permission for a necropsy to be performed had to be obtained from a distance and in consequence the examination had to be conducted somewhat hurriedly and had to be hastily concluded. It was performed on June 16th (12½ hours after death). The abdomen and a portion of the thorax were examined. The body was well nourished and muscular. Post-mortem rigidity was marked. Marks of the sinapisms were present on the epigastrium and in the right half of the left hypochondriac region. Four needle punctures were visible on the skin, one in the middle line in the epigastric region and three close together about one and a half inches from the left costal arch and about the level of the ninth left costal cartilage. The abdomen was somewhat distended. On opening in the middle line a small quantity of blood, about one drachm, was found lying immediately under the subcutaneous tissue in the region of the needle puncture in the middle line. The first organ seen was the liver, the left lobe being enlarged and prominent. The intestines were distended with gas. There was no blood or fluid in the peritoneal cavity. No evidence of peritonitis was present. A few flakes of recent blood stained lymph were found on the surface of the liver at the site of the triple puncture; there was evidence of an attempt at the formation of adhesions. Strong recent adhesions were found between the upper surface of the right lobe and the diaphragm. An area of adhesions was also found low down and behind the right lobe. On tearing through the latter about two drachms of greenish-brown pus escaped. The liver was removed.

Examination of the liver.—The surface was smooth and the capsule was somewhat adherent. It was dull chocolate-brown in colour. In consistence it was soft and like firm putty, pitting readily under the finger-tips. Two natural sulci were present, one on the under surface of the right lobe near the root of the gall-bladder and the other in the anterior border of the right lobe, forming a notch. Near the junction of the posterior and inferior surfaces of the right lobe and well to the right was an area of recent erosion which when closed by adhesions had formed an abscess about one inch by one and a quarter inches deep, from which the pus previously mentioned had escaped. Its walls consisted of friable liver substance which had been rapidly disintegrating and were covered with flakes of thick greenish and greenish-brown pus. On section the liver tissue of the right lobe presented the aspect of a subacute hepatitis. It was soft, friable, and of a chocolate brown colour. No bile staining and no internal abscesses were present. The greater part of the anterior surface of the left lobe was of a slaty-grey colour. Palpation over this area elicited fluctuation and on section a large tropical abscess, a typical so-called idiopathic abscess, was disclosed. Between six and eight ounces of pus escaped. It was largely of an anchovy-paste colour but contained masses of thick greenish pus which also lined its walls. The three needle punctures communicated with the abscess cavity which measured roughly four inches by four inches and to the right was sharply cut off by the division between the two hepatic lobes. The cavity was about half an inch from the surface of the liver and its walls, save on the right side, were very friable. The pus was not offensive, having only a slight sickly odour.

The stomach, which was empty, lay under, and was concealed by, the left hepatic lobe. There were no adhesions present nor was the stomach diseased save for a slight gastritis evidenced by congestion of the mucous membrane. The spleen was slightly enlarged and congested. The splenic pulp was friable. No other morbid condition was present. It was a "febrile" spleen. The small intestine was not opened but appeared to be normal when viewed externally, as did the upper part of the large intestine. The mucous membrane of the lower part of the large intestine and the rectum was distinctly injected. A considerable number of small patches of acute congestion were present which may have been the very early stage of a commencing dysentery or may have been due to the rectal injections of hot fluid. No ulceration, slimy mucus, or blood was present. Specimens of the contents of the bowel from the rectum and of the pus from the abscess cavity were examined but amœbæ were not found. The examination had perforce to be delayed till the following day so that possibly, if present at all, they had broken down and become unrecognisable. There were no perforation of the diaphragm and no communication of any abnormal kind between the thorax and the abdomen. No pus was present in either pleural cavity.

Remarks.—As has been mentioned, the case was of interest clinically from the shortness of the course of the illness considering the great pathological changes found post mortem. Further, the symptoms during life were not proportionate to the severity of the disorder, a state of things by no means rare in cases of abscess of the liver. The question of latent dysentery had to be considered but, as stated, the stools at no time contained blood, mucus, or pus and indeed gave no clue to the liver trouble until the latter became so marked as to be unmistakeable. Dr. Christopherson is inclined to regard the condition as having been pyæmic in nature, infection having occurred through the nose. He saw the case several times before being called in to operate and had been treating the nasal condition. Thus his suggestion is well worthy of consideration but I am unable to regard it as at all probable. True, the mere fact that there was no local inflammatory focus at the supposed seat of infection goes for nothing but I submit that the symptoms, the result of the pus examination, and, above all, the post-mortem findings were opposed to pyæmia. Dr. Christopherson was unable to be present at the post-mortem examination. Had he been so I think he would have concurred with Captain Sterling and myself that the picture presented by the left lobe of the liver was that of a typical tropical abscess such as is usually associated with the presence of the amœba dysenterica. The amœba was present but too much stress cannot be laid on this point, as the organism may merely have found a suitable nidus in the pus. The presence of a second abscess, or rather superficial erosion, does not specially favour the pyæmic hypothesis. Indeed, Captain Leonard Rogers, in his articles on Amœbic Dysentery in India,[1] makes special mention of several cases of abscess forming between the liver and diaphragm and producing superficial erosion as mentioned in the *Calcutta Medical College Records*. In the light of what is stated in the second of these articles it is unfortunate that the small intestine and the upper part of the large intestine were not more thoroughly scrutinised. As mentioned, the examination had to be hurriedly performed and still more hurriedly completed, while the importance of examining these portions of the bowel was not at the moment appreciated. Viewed externally, however, the whole intestinal tract appeared to be perfectly healthy. As stated, marked areas of congestion were found in the mucous membrane of the descending colon, the sigmoid flexure, and the rectum. Were these due to the hot rectal injections or were they evidences of the earliest stage of a commencing dysentery secondary to the abscess of the liver?

Councilman and Lafleur, quoted by Captain Rogers, have shown that the amœba dysenterica can pass across the peritoneal cavity from the bowel to the liver *viâ* the lymphatics on the under surface of the diaphragm. Is it possible for this process to be reversed and for the bowel to be infected secondarily to the liver? The point seems to be worth raising, though the probabilit [illegible] place appears slight when on [illegible] dency of the intraperitoneal [illegible] of things might explain certain cases of hepatic abscess apparently unassociated with dysentery, the infection having taken place by *the mouth and the stomach*.

As regards the fatal and lamentable issue there can be little doubt that the cause of death was nerve shock. No large vein had been punctured nor is it likely that any important nerve had been damaged. The shock was central. Had the patient not been a medical man well acquainted with the dangers of the necessary operation and dreading it exceedingly, I believe, and my belief is shared by the other medical men in attendance, that no fatal result would have occurred from the simple punctures. As a rule, exploring needles can be driven through the liver substance in almost any direction with absolute impunity and usually with benefit if the condition be inflammatory. Here is an example of the inevitable exception which would have been even more distressing than it was had not the post-mortem examination revealed the fact that the liver was in such a state that eventual recovery was in all probability impossible. The disintegrating process was too acute, rapid, and widespread.

One other point may be raised. Did a metazoal parasite play any part in the pathology? There was no sign of any such, no fluke or other worm being seen with the naked eye or microscopically, but the previous eosinophilia has to be borne in mind, and if it does nothing else I think the record of this case goes to show that in any doubtful tropical illness, especially if it be abdominal, the fæces and the blood should be carefully and frequently examined and a differential leucocyte count should be made whenever and wherever feasible.

I am much indebted to Captain Sterling for permission to make use of my notes on this case.

Khartoum.

A CASE OF LINSEED POISONING.

By J. O. HOLLICK, M.B. Durh., M.R.C.S. Eng., L.R.C.P. Lond.

The following symptoms were produced in a patient of mine from the internal administration and the external application to a mucous surface of the seeds of linum usitatissimum, the common linseed or flax.

The patient, a robust man, five feet ten inches in height, and weighing 14 stones, consulted me on May 19th, 1903, for an inflamed and protruding internal hæmorrhoid which had recently come down as a result of sitting on a damp carriage cushion. The pile had become strangulated by the external sphincter and was giving him very severe pain. I ordered him to bed and as he had already applied anodyne ointments and lotions without obtaining relief, also directed that a hot linseed-meal poultice be applied to the inflamed and painful hæmorrhoid. This was done at about 3 P.M. and within four hours afterwards the patient experienced the following symptoms, which I have recorded in his own words.

"To commence with, I experienced a peculiar sensation in the throat and mouth, as though they were lined with velvet, the throat contracting considerably; there was a scaly feeling in the skin of the hands and feet. The skin all over my body, but more particularly on the thighs and legs, went 'anserine,' having the appearance as though a small bladder of water surrounded each hair at its root; the skin changed to a colour between that of red and purple; after this the irregularities on the skin became more pronounced. My face was discoloured and there was a rush of blood to my head. This discolouration of skin was accompanied by irritation. My hearing was affected. I went very deaf and I was also unable to see well. My heart was beating very forcibly and rapidly and I had a strong hysterical feeling. I counted my pulse and timed it to be 120 per minute. I felt on the border of delirium. My chest seemed restricted, particularly at the lower part. These symptoms lasted about three-quarters of an hour and on diarrhœa supervening they were very much mitigated. I then had an attack of vomiting, the vomit being of a dark colour, although I had taken nothing but milk foods for the past 48 hours. After this the symptoms gradually passed off, the velvety feeling at the throat and mouth being the last to disappear. On two previous occasions I had been 'poisoned' by linseed. On the first occasion I was walking through a field in the East of England where labourers were engaged in the operation of stacking the linseed and I ate a few of the seeds. Within three or four hours afterwards I experienced symptoms similar to those narrated above, only to a less degree. I ate about 12 seeds only and the duration of the symptoms was from two to three hours. About two years afterwards I ate two lozenges of 'linseed and liquorice' and the same symptoms were again experienced."

The patient sent for me at 8.30 P.M. and as he resided some distance out in the country I did not see him until 9 P.M.—i.e., two hours after the commencement of the symptoms. He was then in a state of collapse, with quick and feeble pulse, a feeling of nausea, and with cyanosed condition of the face and extremities. His respiration was quiet and the diarrhœa had ceased but he had a marked condition of cutis anserina. He lay curled up on his side in bed and was very prostrate; he at once told me that he had been poisoned by linseed as recognised from his previous experiences. He was given an ounce of brandy in hot water and hot bottles were placed to his feet and body; he passed a good night and on the next day was in normal health again.

The ordinary linseed meal as sold in the shops is obtained by expressing the oil from the seeds and powdering up the marc which remains. The oil is found in the kernel of the seed and in the envelope or testa of the seed is found mucilage only. The fixed oil contains palmitin, stearin, and a glyceride of linoleic acid ($C_{16}H_{28}O_2$), the last in much the greatest quantity. It was probably owing to the presence of the last product in small amount in the linseed meal and its becoming absorbed into the system which gave rise to the symptoms recorded above, the patient evidently exhibiting in an extraordinary degree an idiosyncrasy to the action of the drug. Finding no mention of a similar case in any of the text-books on toxicology and forensic medicine I thought the publishing of the above case might be of interest to the profession and should be glad to hear if any other practitioner has had a similar experience.

Knowle, Warwickshire.

UNUSUAL CASE OF INTESTINAL OBSTRUCTION.

By DUNCAN MACARTNEY, M.A., M.D. Glasg.,
SURGEON TO THE CANCER HOSPITAL, GLASGOW; ASSISTANT SURGEON TO THE WESTERN INFIRMARY, GLASGOW.

At the present stage of our surgical development every case of intestinal obstruction which is operated on successfully is of interest, and if it should happen to possess characteristics apart from the more common forms of obstruction from without as by bands, kinking, tumours, &c., the interest is all the greater. There seem to be fashions in surgery as in other domains of human effort. It used to be the vogue to look out for, and to describe, calculi of wondrous size and shape. Then we pondered on the various modes of closing hernial apertures and where best to leave the sac or its stump. Now the appendix and intestines with their surgical possibilities are receiving their turn. Obstruction from within the bowel of such severity as to lead to abdominal section is comparatively rare. The large majority of the cases of intestinal obstruction that have fallen to my care have been due to bands, contractions of the mesentery making acute kinks in the bowels, or an inflamed gland anchoring a knuckle of bowel, the appendix, or Meckel's diverticulum, and so producing a constricting factor to bring about the obstruction. It might be said, further, that if tuberculous disease of the abdominal glands did not exist we should have very few opportunities of practising intestinal surgery for obstruction.

Treves gives a threefold list of causes of this condition according to the nature of the obstructing agent. "1. Rounded or regularly-shaped bodies that may be considered capable of passing readily through the intestines: pebbles, stones, coins, &c. 2 Sharp pointed bodies and substances of irregular shape that may readily catch in the mucous membrane, or are of an outline that would favour their becoming fixed in the alimentary passage. Such are pins, needles, hooks, plates carrying false teeth, *pieces of bone*, pieces of metal or of porcelain, nails, screws, and other such substances, many of which have been found in the intestine or have passed through it. 3. Indigestible materials of small size which are apt to accumulate until they form huge masses. Indeed, the largest foreign substances found in the alimentary canal have been of this character. They are composed of husks of the oat, vegetable fibres, *grape skins*, or of hairs, or of wool, or of yarn ...... the foreign substance when not passed *per vias naturales*, is apt to remain lodged in special parts of the tube—viz., the stomach, the duodenum, *the lower end of the ileum*, the cæcum, or the rectum."

The case which I have to report illustrates the above quotation in that the obstructive agents belonged to the second and third groups of foreign bodies blocking the canal at the lower end of the ileum.

A woman, aged 42 years, was admitted into Ward No. 21 of the Western Infirmary, Glasgow, on Dec. 23rd, 1901, suffering from symptoms of intestinal obstruction. This was during the Christmas recess when Professor Sir William Macewen was on holiday and I was doing duty for him. The patient stated that she had always enjoyed very good health. There was no history of puerperal fever or of appendicitis. She was married but had no family and had menstruated regularly. She was of a constipated habit and required medicine to get the bowels to move. The motions were never tape-like or streaked with blood but were hard and round like small stones. For some three or four months previously she had been losing flesh and weight without any apparent cause. At the beginning of the period referred to she had an attack of vomiting and obstructive symptoms which lasted for 24 hours the cause of which she did not know. On admission the patient was extremely collapsed and had cold extremities and was almost pulseless. Her temperature was subnormal. She was emaciated and there was marked abdominal distension but no special tenderness; any resistance present was situated towards the left side. Nothing abnormal was felt by rectal examination. Per vaginam the os was found to be large and low and there was some thickening of the right lateral ligament. She had been in her usual health until the morning of the 22nd, when she was suddenly seized with severe and colicky pains in the abdomen, which were worse near the umbilicus and towards the left side. (The seat of obstruction was on the right side near the ileo-cæcal valve.) The pain increased and shortly afterwards she commenced to vomit; the vomit was green at first, then brown, and finally like matter which should come by the bowel with a very foul odour and taste. This vomiting had been continuous since the commencement. There had been no motion of the bowels since the 20th. She had been given castor oil and other purgatives by her attendant, Dr. Douglas Brown of Partick. Enemata had produced no result. Prior to her admission Dr. Brown administered a hypodermic injection of morphia to relieve the pain. Urine had been passed freely.

When I was called to her she was in a state of extreme collapse, almost pulseless, and with the pinched face so well known in such abdominal cases. It seemed a hopeless case, but whatever chance there was for her lay in operation and this was decided on. A mixture of chloroform and ether in equal parts was administered which she took rather badly, the breathing being laboured, the face bluish most of the time, and the pulse extremely feeble. The abdomen was opened in the middle line from the umbilicus downwards. When the peritoneum was divided coils of small intestine presented themselves much distended. Inserting the hand I searched quickly in the ileo-cæcal region, then towards the other flexures of the colon, and finally in the pelvis. (As a rule, in cases of intestinal obstruction collapsed small intestine is found there and it forms a good starting-point in the search for the source of obstruction.) I found no collapsed bowel there and returned to the ileo-cæcal region and on more careful examination, by bringing the parts to the wound, found a few inches of ileum in its normal state just above the valve. Where the normal bowel below and the dilated portion above joined there was a cylindrical plug nearly three inches in length, the upper part, soft and pultaceous, resting on a base of hard, irregular shaped bodies lying on each other like the sticks on a crow's nest. By careful manipulation and [illegible] hard bodies I managed to move [illegible] valve into the colon, the softer, [illegible] owing by the action of the intestines alone. In the manipulation the serous lining at one small point was torn, not by the body within penetrating, but from the tension. A couple of fine Lembert's sutures were inserted for fear of any bad result. Had the patient been possessed of any reserve of strength I should have cut in and removed the cause of obstruction, but time was of vital importance and the nearness of the seat of obstruction to the colon determined the mode of procedure which was the quicker. The wound in the abdomen was sewed up and the usual dressings were applied. She was taken to bed with a very poor pulse and in an extremely exhausted state.

For two or three days she remained in a very weak state but gradually she began to mend and made a perfect recovery. Her temperature was subnormal for three days after the operation. When the bowels moved the excreta were carefully examined and a dozen small bones were found with a large number of raisin-skins. The patient denied having eaten chicken, rabbit, or anything likely to have contained bones of this kind. The bones were sent to Dr. J. F. Gemmill at the anatomy rooms of the university who gave me a photograph of them and stated that they were: one first phalanx of the fourth toe of a not very large common fowl; one second phalanx of the third toe; two third phalanges (right and left) of the second toe; one second phalanx of the outer toe; two third phalanges (right and left) and two fourth phalanges (right and left), of the outer toe; part of fibula; and scale from the back of the ilium.

Before the patient was dismissed she volunteered corroborative information that her husband and herself had two days before her illness dined off a chicken (feet and all), having for dessert a piece of "Scotch cake"—her term for what is more familiarly known here as "currant-bun" The ingestion of the chicken's feet marks a departure in domestic economy that is not likely to be followed by the laity at large and need not even point a moral.

Glasgow.

A BRIEF EXPERIENCE IN ABDOMINAL SURGERY.

BY B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

DURING seven consecutive weeks I had under my care in hospital and private practice a succession of abdominal cases that for number and variety are perhaps deserving of record. The mere enumeration of such a series illustrates vividly the enormous increase that has occurred in the last few years in the work that the surgeon is called upon to do.

The following is a summary of the operations. There were four cases of intestinal obstruction, all due to growth in the

large or small intestine. Of these two recovered and two died. There were 18 operations upon the stomach, four for malignant disease, with one death, and 14 for simple diseases with no death. There were six cases of abdominal hysterectomy, five for fibroid and one for double ovarian disease with implication of the uterus. There were two ovarian cysts, one with a twisted pedicle. There were three cases of ventrofixation and colporrhaphy; there was one case of myomectomy for pedunculated fibroid; and one case of extra-uterine gestation. All these cases recovered. There were nine operations upon the gall-bladder and bile passages. Among these were two cases of duodeno-choledochotomy with cholecystectomy, there were three cases of cholecystectomy, and three cases of cholecystotomy. All these patients recovered. There was one exploratory laparotomy, in which gall-stones and advanced malignant disease of the liver were found. This patient, a feeble old woman, died in three days. There were two cases of removal of the appendix for recurring appendicitis; both patients recovered. There was one case of appendicostomy (Weir's operation) done for the purpose of flushing the large intestine affected with muco-membranous inflammation. The patient recovered. There were three cases of colectomy; in one the sigmoid flexure was removed for growth, a loop of small intestine adherent to the growth was also removed; in the second about three feet of the ileum. the cæcum, the ascending and a portion of the transverse colon were removed for malignant disease; in the third a growth was removed from the transverse colon. All these patients recovered. A portion of the transverse colon was also removed with the malignant growth in the stomach in one case. There were one case of Talma's operation (epiplopexy) for ascites and one case of inguinal colotomy. These patients recovered. This makes a total of 52 operations, with four deaths, all the deaths being in malignant cases. For the privilege of admitting many of the hospital cases I am indebted to Mr. E. Ward. Tables I., II., III., and IV. show the most important cases.

NOTE ON GUAIACOL CARBONATE IN THE TREATMENT OF MEASLES.

BY DAVID MONTGOMERIE PATON, L.R.C.P., L.S.C.S. EDIN., L.F.P.S. GLASG.

FOR some years I have used guaiacol carbonate in the treatment of measles with such beneficial results that I feel I can now recommend the remedy to the profession. The idea was suggested to me by the results obtained by its use in bronchial catarrh with fever. For the purposes of treatment I divide bronchial catarrh into two classes—one with fever and the other without rise of temperature. For the first, unless arising from influenza, I find guaiacol a specific and it is many a day since I have had to order an expectorant or other like mixture for a case of bronchial catarrh with fever. For the catarrh without fever it is regrettable that no such specific exists and that the usual treatment has to be administered. The action of the drug on a feverish bronchial attack is to lower the temperature rapidly and to reduce the case to one of an ordinary character without fever. Seeing how successful the treatment had been in such cases a trial of it was made on the catarrhal conditions associated with measles. From the very first it was a success and the rapidity and thoroughness of the recovery were very marked. This was due to the complete abortion of the usual respiratory troubles, so that while the patients had measles, some very severely, with temperatures between 104° and 105° F., they had nothing else, and when the temperature fell to normal they were practically well and in no case have sequelæ been seen.

The following case is an example of what it is capable of doing. The patient was seven years of age, a poorly-grown, delicate, catarrhal subject with hypertrophied tonsils and post nasal trouble. He had just returned from a trip to the northern ports and had brought the measles infection home with him. He had been sent away for the trip to get rid of a persistent catarrh with cough which had troubled him for some months. The prodromal symptoms lasted for four days and he was put on the guaiacol treatment when the rash appeared. The case was a fairly severe one, the temperature being over 103°, but in two days it was all over and in two days more he was up and about the room as well as he ever was. Not only had he no bronchial catarrh (and he has already had two attacks of broncho-pneumonia), but the catarrh which had so long troubled him disappeared and he emerged from the illness in better health than he has ever had.

The treatment seems to have no modifying effect on the measles itself, but it limits the case to measles and that alone without leaving any of the usual sequelæ. For vomiting, which rarely occurs, a little bismuth may be added to the guaiacol and to that again a little Dover's powder if required for diarrhœa. The treatment is begun when the diagnosis is made and continued in full doses till the temperature has fallen to normal, a reduced quantity being given for two days longer to make sure of the result. The dose is calculated at one drachm per diem in powders of ten grains every three hours for adults and children in proportion. The powder is readily taken by children and all the more so if an equal amount of powdered sugar is added. No unfavourable symptoms have ever been seen during its administration which could in the slightest degree be attributed to the treatment, in no case has it failed to abort the bronchial catarrh, and there have been no deaths.

Melbourne.

A CASE OF OBSTINATE DYSPEPSIA FOLLOWED BY PERSISTENT HICCOUGH.

BY JAMES GILROY, M.B., C.M., L.F.P.S. GLASG.

ON Jan. 7th, 1903, I was called to a man, aged 60 years, suffering from severe vomiting and intolerance of food or drink. He told me that as he had not felt well he had gone to Harrogate for a change from here but that he returned much worse than when he left. I ordered poultices to be applied to the stomach, bismuth mixtures, hypodermic injections of morphia, ice to suck, and champagne at intervals. My attendance lasted until Jan. 28th and latterly the stomach-tube was used for lavage. The vomited material was at times quite black and for some eight to ten days I had great apprehensions owing to the supervening of a persistent hiccough. It seemed to defy everything. Hyoscyamus and pressure on the phrenic nerve gave only temporary relief. I found, however, that it was amenable at once to the ordinary doses of tincture of jaborandi with a little spirit of nitrous ether. Whether this points to a uræmic origin I must leave to others to decide. I can only say that the patient was never drowsy. Sleep was the one thing he could not get. Since the above date the patient has passed through a similar attack from Sept. 6th to Oct. 15th. He is now convalescent but the jaborandi again did excellent service in arresting hiccough.

Waterbeck, Dumfriesshire.

NOTES OF A CASE OF PARALYSIS OF THE UPPER EXTREMITIES, PROBABLY DUE TO DIPHTHERIA, ACCOMPANIED BY A RASH (SEPTIC).

BY R. E. P. SQUIBBS, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a girl, aged three and a half years, and was first seen by me on August 7th, 1903. She had always enjoyed fairly good health and the family history was good but she had lost two brothers in infancy. Three weeks before the present seizure she had returned from the seaside and had appeared to be well up to August 4th, but on questioning the mother I found that the child had seemed different from usual and slightly ailing. She was said to have fallen on August 5th as if in a fainting fit. Her condition on the 7th was as follows. She was unable to move her upper limbs, the left arm being even more helpless than the right and the first to be affected. The temperature in the axilla was 99 8° F. The child was slightly sick. Her skin was moist and flushed. I gave her some sodium salicylate and ordered the joints to be wrapped in cotton-wool, on which some castor oil was to be poured. On the 8th the temperature in the axilla was 100°. There was no power of movement in the upper limbs but sensation seemed to be unaffected. The child had passed a restless night and there was a well-marked flush upon the chest. An enema was given as the bowels were confined. On the 9th the temperature in the axilla was lower. There seemed to be more ability to move the arms. There was a well-marked scarlatiniform rash over the chest and abdomen. On the 11th there was a well-marked scarlatiniform rash over the chest, back, arms, and thighs. There was no sore throat. There were much restlessness and sleeplessness and the bowels were constipated. The patient took a fair amount of liquid nourishment; she cried out if her arms were moved but she could move the fingers of the right hand. I gave small doses of bromide of potassium. On the 18th the rash had disappeared and the patient felt better. Both arms were still paralysed and attempted movement caused her to cry out. The right arm was improving. On the 24th the patient had much improved except for the paralysis of the left arm and paresis of the right arm, though she could move the fingers and wrist. This day I met in consultation Dr. Lewis W. Marshall who formed the opinion that this was a case of neuritis following diphtheria, the rash being of a septic nature. He also recommended the use of strychnine and iron in small doses. By Oct. 16th, using electricity and tonics, I had succeeded in a great measure in restoring the power of the right upper limb but I regret to say that the left arm is almost completely useless, as the patient is only able slightly to move the wrist and the fingers.

MANCHESTER ROYAL INFIRMARY.

PSEUDO (?) ANGINA PECTORIS OCCURRING IN CASES OF MITRAL STENOSIS.

(Under the care of Dr. GRAHAM STEELL.)

THE two following cases have been under observation from time to time at the Manchester Royal Infirmary for several years. For the notes of them now published we are indebted to Dr. M. Stanley Wood, house physician.

CASE 1.—This patient is a woman, 22 years of age. She had attacks of rheumatic fever at five years of age, at 15 years, and again at 19 years. She often suffered from "pains in the joints and sore throat" as a child and has been "short of breath" on exertion as long as she can remember. She had "swelling of the feet" during the last rheumatic attack and several times since. On auscultation a very constant presystolic murmur is heard at the apex of the heart. The history of her anginal attacks is as follows. She first complained of pain in the "region of the heart" at 11 years of age. She has had pain somewhat frequently since that time but only in the region of the heart until five months ago, when the pain commenced to shoot up to the left shoulder and then down the arm on the left side. One month ago the pain commenced to shoot up to the left side of the neck and face. She has not been quite free from "pain round the heart" for two months. The leading features of an anginal attack are as follows. The pain usually begins from 7 to 9 P.M.; it comes on gradually and is preceded by an attack of dyspnœa. It first commences in the region of the heart and is described by the patient as "cramp of the heart." This pain gradually assumes more of a "dragging" character than one of constriction; at the same time "shooting, tingling" pains begin to pass to the left shoulder and down the left arm, sometimes to the elbow only, sometimes to the ring finger and little finger. The right shoulder and arm have never been affected. During recent attacks the pain has also passed up to the left side of the neck and face, the pain here being similar to that in the arm, of a "shooting, tingling" character, at the same time the parts affected feeling as though "asleep." After a moderately severe attack of pain there is tenderness on pressure from the first to between the third and fourth dorsal spines. Superficial tenderness starts below in the middle line about two inches above the umbilicus; it extends upwards on the left side to the neck and lower part of the face. There is no superficial tenderness on the right side. At the back there is a narrow area of tenderness extending from the second dorsal spine outwards to the back of the left shoulder and down the inner side of the left arm as far as the elbow. Below this from the sixth dorsal spine another narrow area with ill-defined lower border passes to join the superficial tenderness in front. An area which is not tender is thus mapped out extending behind from the second to the sixth dorsal spine and bounded in front by the anterior axillary line. The pain passes away gradually, usually leaving the patient towards 1 or 2 A.M. At the same time the breathing improves. During the attack the patient is flushed and is obviously in great pain, and her breathing is difficult. The temperature is not raised and a sphygmogram taken during the attack shows no change.

CASE 2.—This patient is a woman, aged 24 years. She had chorea at 13 years of age and rheumatism at 19 years. She had "always" complained of "shortness of breath." Her feet became "swollen" 18 months ago. On auscultation a markedly constant presystolic murmur is heard. The history of her anginal attacks is as follows. She first complained of "pain round the heart" three years ago and has had repeated attacks since. The pain shoots down both arms and to the left side of the head. The leading features of an anginal attack are as follows. The pain begins more or less suddenly in the evening, lasts a few hours, and goes away gradually. The patient is always "short of breath" during the attack. The pain commences by a feeling of "tightness round the heart," followed by a "dull dragging pain"; it then shoots upwards more commonly to the left, sometimes to the right shoulder; from here the pain shoots down usually to the ring finger and little finger of the left hand but sometimes to all the fingers. More rarely the pain passes to the left side of the neck and face but never to the right side. More rarely still the pain goes to the right shoulder and down to the ring finger of the right hand. The pain is of a "shooting" character here and intermittent. After a fairly severe attack of pain there is tenderness on pressure from the first to between the third and fourth dorsal spines. Superficial tenderness commences below in the middle line at the level of the seventh costal cartilage and passes upwards and outwards on the left side. It is bounded above by the left clavicle. At the back the tenderness commences at the level of the second dorsal spine and is bounded below by the ninth dorsal spine; it passes outwards to join with the tenderness in front. There is also a narrow area of tenderness extending from the second dorsal spine to the back of the right shoulder but not into the right arm; on the left side the tenderness extends down the inner side of the arm as far as the elbow. During the last few attacks the patient has had she has complained of severe headache over the left eye. During a very severe attack the pulse-rate increased to 160 but dropped back to 72 in the course of an hour. The nitrites have been administered but little benefit has resulted. Only morphia gives relief. The striking similarity of these accounts given by patients unknown to one another is of much importance, the distribution and character of the pain being almost the same in both cases.

Remarks by Dr. STEELL.—Angina pectoris has long been associated pathologically with changes in the coronary arteries interfering with the due supply of blood to the heart muscle. During recent years patients—young and female—presenting the typical signs of mitral stenosis have been under my care in the Manchester Royal Infirmary who have complained of pain bearing so close a resemblance to angina pectoris that it seems unreasonable to withhold from the same symptoms the same name. In atheromatous disease of the aorta with aortic incompetence angina pectoris in typical perfection is common enough, but in such cases—in my experience without exception—the coronary arteries are involved, their orifices being commonly caught, as it were, in the disease and greatly narrowed. If angina pectoris do indeed occur in cases of mitral stenosis in young and female subjects the fact seriously weakens the dogma that angina pectoris implies narrowing of the coronary arteries in one form or another. Preconceived ideas in the matter have, I doubt not, prevented me recognising the genuineness of anginal symptoms in cases of mitral stenosis previously and it is perhaps the accidental circumstance of having two cases of the kind in the wards at the same time—in patients in different wards and having no opportunity of collusion—that has forced me to reconsider my belief in the matter.

Another fact with regard to the pain of heart disease that has recently likewise forced itself upon my attention is the very frequent complaint of præcordial pain by the young subjects of dilatation of the heart as a result of rheumatic myocarditis. This variety of pain is altogether different from angina pectoris and in no way suggests it. The actual pain seems to be less severe and acute than angina and not to be paroxysmal but nevertheless it is a source of very great distress to the sufferers. There is no arm pain and the pain is referred directly to the præcordium. I have long been familiar with this variety of pain and in the wards designated it—I think after the teaching of an old master—"cardiac pain" to distinguish it from "angina pectoris." The subject of referred visceral pain and the direct sensitiveness of the viscera is one too large to be entered upon here. The cases bear out on the whole the observations of Dr. J. Ross, Dr. J. Mackenzie, and Dr. H. Head on referred pain. In both cases a marked feature was the persistence of the presystolic murmur and the absence of systolic murmur. "In cases of this kind referred pain is not usually present." Moreover, the following segments associated with the aorta would seem to have been implicated: Inferior laryngeal segment corresponding to the transverse part of the arch; the first, second, and third (fourth?) dorsal segments, and, perhaps, in some measure, the third and fourth cervical corresponding to the ascending arch. The supra-orbital headache in the second case, again, would point to the influence of the second and third dorsal segments. The auricle "refers" to the fifth, sixth, seventh, and eighth (ninth?) segments and the pain and tenderness in this distribution is not surprising. It is the pain "referring" to the aortic segments that, in the cases narrated, is anomalous. I would mention only the statement of Nothnagel that of 1500 cases of valvular disease of the heart "there was but a single case in which angina pectoris occurred in connexion with mitral stenosis" (Osler: "Angina Pectoris").

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Behaviour of Cancer in Nerve Areas.—The Estimation of Bile Salts in the Urine.—The Agglutination Reaction in Tropical and Asylum Dysentery.

A MEETING of this society was held on Nov. 17th, at the Pathological Laboratory, King's College, Dr. R. T. HEWLETT being in the chair.

Mr. G. L. CHEATLE said that there were two points to which he would wish to call attention with regard to the Behaviour of Cancer in Nerve Areas. The first of these was the relation which rodent ulcer had in its spread to underlying muscles He showed a series of photographs and demonstrated that rodent ulcer when spreading tended to map out certain muscles. The second point was that rodent ulcer did not tend to spread in an area which was anæsthetic. He showed a series of photographs in which although the ulcer had spread rapidly into the areas which were not anæsthetic yet it had remained stationary in the area of skin which had been rendered anæsthetic by the destruction of the nerve

Dr O. F. F. GRÜNBAUM gave a description of a Method of estimating Bile Salts in the Urine. He said that the difficulty of testing for bile salts in the urine was considerable except by the test employed by Matthew Hay which consisted in sprinkling flowers of sulphur on the surface of the urine. If the flowers of sulphur sank bile salts were present, this being due to the diminished surface tension. No other bodies except bile salts gave rise to any marked diminution of surface tension. He therefore considered that if the surface tension could be measured it would give a quantitative result of the amount of bile salts present. After trying various methods he found the following successful. The number of drops of normal urine coming from a graduated *pipette, which was fitted with a specially drawn quartz* needle so as to be readily cleaned, was counted and found to be 123 Sodium glycocholate was now added so that the urine contained 1 part in 10,000 The pipette now delivered 140 drops. When two parts of sodium glycocholate were added to 10,000 of urine the pipette delivered 154 drops, and in this way a table was constructed so that the number of drops coming from the pipette gave the quantity of bile salts present in the solution.

Dr. HEWLETT communicated a paper upon the Agglutination Reaction in Cases of Dysentery. After a review of the literature he said that he had tested a number of cases of dysentery for the agglutination reaction upon a strain of the bacillus dysenteriæ which he had received from Professor Flexner. The results [illegible] the cases of dysentery with one [illegible] reaction, while two or three cas[illegible] reaction. The case of dysentery which reacted was of the amœbic type, so that the reaction seemed to be contradictory though there might have been a double infection. Two fresh cultures of the bacillus dysenteriæ, a "Shiga" *and a "Flexner" strain respectively, having been received* from Professor Flexner, Dr. Hewlett had made further tests. The results were much more promising. Of four cases of dysentery three reacted markedly and the fourth slightly; an amœbic case did not react at all. Two cases of *asylum dysentery also reacted well. It was noteworthy that* these cases reacted with the Flexner strain only and not with the Shiga strain.

CLINICAL SOCIETY OF LONDON.

Myositis Fibrosa.—Measles with Coma.—Pernicious Anæmia with Unusual Features.

A MEETING of this society was held on Nov. 13th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. F. E. BATTEN read a paper on a case of Myositis F[illegible] the pathological examinat[illegible] aged six years, the second o[illegible]was healthy at birth but when nine months old the mother noticed that the back was becoming curved and the legs could not be straightened. The contractions gradually increased and when six years old he was in a rigid flexed position, so that any attempt to extend the legs brought the trunk into a sitting position. The head was drawn down to the right side by extreme contraction of the right sterno mastoid and the recti abdominis muscles were greatly contracted and of cartilaginous hardness. The upper and lower extremities were also contracted in a flexed position. There was no evidence of any disease of the nervous system All the muscles in which the contraction was not extreme reacted to a weak faradic current. No *relaxation of the contracted muscles occurred when the* boy was placed under chloroform. The pathological examination of the nervous system revealed nothing abnormal. With regard to the muscles, the right sterno-mastoid was almost completely converted into tendinous material and fully one-half of the recti abdominis muscles was tendinous. In the muscular portions of these muscles and in the other muscles of the body examined there was a very considerable amount of fibrous tissue between the individual muscle fibres. Many of the muscular fibres were atrophied and muscle showed *considerable fatty degeneration* in places. The question of *etiology* was then considered but no factor could be found to account for the disease. The close relationship of the disease to myositis ossificans was discussed and it was mentioned in support of this view that the great toes were shorter than the second, third, and fourth toes in this case. The question whether the tendon which formed so large a portion of certain muscles was a new formation or only a relative increase owing to the contraction of the muscle was then dealt with and Dr. Batten favoured the view that there was but a relative increase owing to the contraction of the fibrous portion of the muscle. The paper was illustrated by lantern slides and drawings.

Dr. G. NEWTON PITT communicated a case of Measles with Coma. The patient, a male, aged 19 years, in good health, was taken ill on March 10th, 1899, and the eruption developed on the next day. His temperature was high, reaching on one occasion 105° F., but he was not seriously ill until the 15th, when he became *violent and noisy, and on the 17th* he became collapsed and comatose. His tongue was not dry, the rash was well developed, the pulse was 110, and the temperature was 103·4°. On the 18th the temperature and pulse fell. There was more or less coma for four days but he made a good recovery. For many months his memory was defective. The development of coma in measles was a *rare event. It might be due (1) to toxæmia*; (2) to meningitis when the cause was either ear trouble or tubercle; (3) to thrombosis often leading to hemiplegia; (4) to disseminated encephalitis; or (5) to anterior poliomyelitis or disseminated myelitis which was often associated with delirium and coma at the onset. Cases which illustrated some of these causes were quoted. It was interesting to note that out of 200 cases of hemiplegia in children 11 had started in an attack of measles. Some of these were thrombotic in origin. Dr. Pitt did not regard his case as one of toxic origin but due to a local encephalitis which cleared up entirely, leaving only the temporary amnesia He referred to two cases under the care of Mr. E. O. Kingsford. One patient was a child, six years old, who a few days after the onset of an apparently mild attack of measles became comatose and remained so for nine days but who *gradually recovered, the only trace of mischief being a* slight incoördination of the fingers of the right hand. Another case was that of a girl, aged seven years, who recovered excepting that she remained permanently deaf. A similar case was recorded by Dr. Dawson Williams; the patient recovered *after ten days of coma* but a spastic condition of the limbs persisted due to disseminated encephalitis. —Dr. ALEXANDER MORISON alluded to the case of a girl, aged ten years, in whom the temperature was not very high and the rash not abundant; bronchitis supervened with a comatose condition and the child died. Such a case seemed *to justify the popular belief that cases with a full eruption* ran a most favourable course —Dr. SIDNEY P. PHILLIPS could recall many cases of measles in children associated with coma but not in adults. He presumed that the condition of the urine was normal. He would not attach much impo[illegible]greed with D[illegible] the coma in[illegible]possible to distinguish between an encephalitis and a thrombosis; the former was, in point of fact, attended by thrombosis of the smaller vessels.—Dr. WILLIAM HUNTER had seen coma associated with scarlet fever in which there was a probability that encephalitis had occurred.—Dr. PITT, in reply, remarked that pathologically encephalitis was no doubt a diffuse thrombosis but clinically the two conditions were separable.

Dr. WILLIAM PASTEUR communicated a case of Pernicious Anæmia. The patient was a well-built man, aged 24 years, who had had to leave work three weeks before on account of weakness and breathlessness. On admission he was suffering from profound anæmia, with sallow muddy complexion, and *there was some oozing* of blood *from* the gums. His teeth and mouth were in good condition and had never given him trouble. The heart was slightly enlarged and there were hæmic murmurs. The spleen was not enlarged. Sight had failed gradually since the onset of his illness. He was found to be suffering from severe double hæmorrhagic neuro retinitis with patches of exudation. There was frequent sickness throughout his stay in hospital. The temperature rose slightly in the evening but only once reached 100° F. The blood exhibited marked oligocythæmia but without high colour index and there was well-marked leucopenia with *relative* lymphocytosis, the leucocytes numbering only 2600 per cubic millimetre ten days before death, which occurred exactly seven weeks after the attack of faintness. No megaloblasts or poikilocytes were observed at any time. Sections of the liver gave a marked Prussian blue reaction. The spleen gave a slight reaction and the testis a very marked one. Chemical analysis showed that the amount of iron yielded by the liver was more than six times the average and that it exceeded the amount obtained from the spleen. The case presented several unusual features, notably the absence of nearly all *the blood changes commonly present* in the pernicious anæmia *of Addison. The short duration* of the illness and the intensity of the fundus changes were also unusual features. The profound hæmolysis revealed by the chemical examination of the organs afforded the only strong argument in favour of this case being classed as one of true pernicious anæmia.—Dr. HUNTER said it would have been interesting to have known the state of the bone marrow in this case as the blood changes were not those usually associated with the true Addisonian form of pernicious anæmia. The absence of poikilocytosis was particularly an unusual feature. The great rapidity of the case, its sudden onset, and the nature of the blood changes would rather incline him to place the case among that group of anæmias of septic or traumatic origin.—Dr. NORMAN DALTON referred to a similar case of a man in whom there were great oligocythæmia and also a definite septic focus in the shape of a fistula leading from the gums to the palate. A noteworthy point in connexion with the case was that when the sepsis was detected there was a sudden rise in the number of leucocytes.—Dr. PASTEUR replied that he was unaware of any septic trouble in his case and said that his diagnosis was based more especially on the post-mortem findings in the liver and the spleen.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Pathological and Microscopical Specimens.—Intestinal Obstruction.

A MEETING of this society was held on Nov. 12th, Mr. RUSHTON PARKER, the President, being in the chair.

Mr. F. T. PAUL showed: 1. A large Tumour of the Parotid Gland removed from a woman, aged 62 years. The tumour had been present for 25 years. On microscopical examination it was found to have become carcinomatous. 2. Sections of a rare variety of Carcinoma of the Breast, characterised by rapid necrosis and ulceration; it was of a very malignant type. 3. Two specimens of the pylorus which had been removed by operation; one was a fibrous stricture and the other was a malignant one.

Mr. G. P. NEWBOLT showed a specimen of Malignant Disease of the Prostate from a man, aged 63 years. A polypoid excrescence projected into and blocked the neck of the bladder.

Dr. K. A. GROSSMANN exhibited: 1. Specimens of Tænia Solium obtained from a dog. He demonstrated its structure by means of lantern slides and showed that it differed in several respects from the human parasite. 2. Microscopic specimens of a Pigmented Excrescence from the Pupillary Region of the Calf.

Mr. R. W. MURRAY exhibited a section obtained from the Breast of a female patient, aged 55 years. The clinical signs and naked-eye appearances pointed to a carcinomatous condition but microscopical examination revealed a large number of giant cells and no definitely carcinomatous structure, so that a diagnosis of tuberculosis had been made. —Mr. MURRAY also exhibited a portion of Intestine which in the course of an operation for short-circuiting the gut he had occluded at either end and retained within the abdominal cavity. Two years after this operation the portion of intestine so occluded was enormously distended with offensive muco-purulent fluid and led to the death of the patient.

Mr. J. DOUGLAS CRAWFORD showed (1) a specimen of a large Cystic Goitre removed from the thyroid isthmus; and (2) two small Lateral Lobes of a Prostate enucleated for Urinary Obstruction.

Dr. W. T. D. ALLEN showed a specimen of Ulcerative Endocarditis which was associated with Tuberculosis of the Cerebral Meninges and the Lungs.

Dr E. E. GLYNN exhibited (1) a specimen of Pontine Hæmorrhage, and (2) specimens illustrating Fat Necrosis in the Omentum.

Sir WILLIAM M. BANKS showed an Enchondroma removed by operation together with a portion of the scapula from which it had originated.

Mr. PAUL read a note upon a case of Intestinal Obstruction due to a Large Gall stone successfully removed from the upper part of the ileum The patient was a woman, aged 62 years, who was suddenly attacked with vomiting and intestinal obstruction. Three days later she had copious fæcal vomiting and a flat abdomen. A diagnosis of obstruction high in the intestine was made which was thought to be probably due to a gall stone because of a history of previous symptoms She had never had typical attacks of gall stone colic but had complained for a considerable time of a dull pain in the right hypochondrium She made a rapid and complete recovery.—Mr. W. THELWALL THOMAS mentioned two cases of a similar nature in neither of which had there been previous jaundice. He stated that in the published cases the obstruction had been found most commonly in the ileum, indicating ulceration primarily into the duodenum. Ulceration into the colon was rare.—Mr. NEWBOLT showed a large biliary calculus which he had removed some months before from the same portion of the intestinal tract and which had also caused complete obstruction.

Dr. GLYNN described two specimens of Secondary Diffuse Carcinomatosis of the Spleen and discussed the microscopic appearances.

The following members took part in the discussions: The PRESIDENT, Mr. PAUL, Dr. W. ALEXANDER, Mr. F. C. LARKIN, Dr. F. H. BARENDT, Mr. THELWALL THOMAS, Dr. W. B. WARRINGTON, Dr. A. S. F. GRUNBAUM, Dr. N. RAW, Mr. HAMILTON, Dr. H. BRIGGS, and Mr. K. W. MONSARRAT.

The following card specimens were exhibited:—

Mr. THELWALL THOMAS: (1) A Piece of Cedar-wood Pencil, one and a quarter inches long, removed by Suprapubic Cystotomy; and (2) a specimen of Cystic Mastitis.

Dr. GLYNN: A specimen showing Rupture of a Caseous Bronchial Gland into the Trachea causing Asphyxia.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Some Surgical Operations in General Practice.—Cæsarean Section.—Removal of the Prostate and Prostatic Urethra.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 6th, Mr. C. RICHARDSON, the President, being in the chair.

Mr. J. STEWART related the following cases: Case 1. Disease of the Hip-joint in a child, aged 11 years. There were a sequestrum of the acetabulum, erosion of the cartilage of the head of the femur, and putty-like material extending down the shaft for five inches. Excision was performed and recovery ensued. Case 2. Double Femoral Hernia in a female, aged 21 years, both of which were operated upon at the same time. The left presented the curious condition of a sac within a sac separated by fluid. A radical operation was performed with a good result. Case 3 Pott's Fracture of the Ankle in which the inner malleolus failed to unite. Subsequent division of the fibula below the seat of the fracture and suturing of the inner malleolus to the shaft were performed with a good result. Case 4. Papilloma of the Bladder in a man, aged 64 years. Suprapubic cystotomy was performed and a sessile growth covering a space of the size of half a crown was removed with a perfect result. Case 5. Curettage of the Uterus in a patient, aged 24 years. Complete suppression of the urine supervened with hiccough, diarrhœa, and death on the fifth day. Case 6 Very Acute Appendicitis (Fulminating) in a man, aged 21 years. The acute symptoms subsided. The appendix was removed at the end of six weeks. Complete recovery followed. Case 7. Fulminating Appendicitis in a girl, aged 16 years, which was caused by a blow over the appendix, resulting in a small tear, exactly over one of two concretions. On concretion was of the size of a pea and the other was of the size and shape of an almond. The appendix was removed on the third day. Severe hæmorrhage from the lower angle of the wound (in which was a gauze drain) occurred on the fifteenth day. Complete recovery ensued.—Mr. B. G. A. MOYNIHAN and Mr. R. LAWFORD KNAGGS discussed the cases and Mr. STEWART replied.

Dr J. B HELLIER read a paper on the Modern Operation of Cæsarean Section by the Conservative Method. He showed two patients on whom it had recently been performed. Both mothers and both children were saved He sketched the development of the operation and dwelt on the confidence with which it might be undertaken when the patient came under care before labour had commenced.—The PRESIDENT and Dr. F. A. DE T. MOUILLOT discussed the paper and Dr. HELLIER replied.

Mr. MOYNIHAN read a paper upon a series of 12 cases of Suprapubic Removal of the Prostate and of the Prostatic Urethra for Senile Enlargement of the Prostate. The first operation was performed in September, 1901, and was accidental. During the stripping of the prostate the separation of the gland proceeded very rapidly and almost without warning the whole gland came away with the urethra The patient recovered well from the operation and was now, and had always been, perfectly well. He passed urine in an absolutely normal manner. 11 similar cases had been operated upon deliberately since; there had been one death, in a very feeble old man with advanced cystitis. The largest prostate weighed six and a half ounces. In four cases a stone had been removed as well as the prostate. The details of the operation and of the after-treatment were fully described.—Mr. **STEWART**, Dr. J. **IRVING**, and Mr. **LAWFORD KNAGGS** took part in the discussion and Mr. **MOYNIHAN** replied.

The following cases, pathological specimens, &c., were shown:—

Dr. E. C. **CROFT**: Large Urinary Calculus from a Female Bladder.

Dr. C. M. **CHADWICK**: (1) Unusual Enlargement of the Spleen associated with Cardiac Disease; (2) Enlarged Spleen in a Child; and (3) two cases of Graves's Disease.

Mr. H. **LITTLEWOOD**: (1) A patient operated on for Hydatid of the Spleen (Bond's method); (2) a patient operated on for Enlarged Thyroid; (3) Parts from Tubal Gestation; (4) Ovarian Cyst with a Twisted Pedicle; (5) Fibroid of the Uterus and Cervix (weighing seven pounds) removed by Abdominal Hysterectomy; (6) two specimens of Perforated Gastric Ulcer; and (7) Encysted Hydrocele of the Testis.

Dr. T. **CHURTON**: (1) A case of Splenic Leukæmia; (2) a case of Splenic Anæmia; and (3) a case of Splenic Anæmia with Cirrhosis of the Liver (Banti's disease).

Mr. **MOYNIHAN**: A series of specimens of Complete Prostatectomy.

Mr. H. **SECKER WALKER**: Some Ophthalmic Specimens.

Mr. W. H **BROWN**: (1) Enterectomy and Colectomy in the same patient; (2) a Growth of the Cæcum; (3) a series of Appendices; and (4) Congenital Tumour over the Sacrum.

Dr. T. **WARDROP GRIFFITH**: (1) Some cases of Rodent Ulcer treated by the X Rays; and (2) two cases of Lichen Planus.

Mr. G. P. **ANNING**: A case for Diagnosis (? Hydrocephalus).

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

Cytology of Serous and Sero-fibrinous Effusions.—Exhibition of Specimens.

A **MEETING** of this section was held on Nov. 6th, Dr. H. C **EARL**, the President, being in the chair.

The **PRESIDENT** delivered an address on the Cytology of Serous and Sero-fibrinous Effusions. He described the methods of obtaining and making microscopic preparations of the cells from effusions and related the results which Widal and others obtained by cytological examination of effusions from the pleura, pericardium, and peritoneum, of articular fluid and of hydrocele fluid, as well as of the cerebro-spinal fluid. He considered that the diagnostic value of a predominance of lymphocytes in a pleural effusion as a sign of the tuberculous nature of the effusion was very great but that the results of examinations of pericardial and peritoneal effusions were not sufficiently numerous or sufficiently consistent to warrant any precise conclusions at present. He further considered that cytological examinations of fluids from joints and from hydroceles had given results of some diagnostic value and that an increase of cells with predominance of lymphocytes in the cerebro-spinal fluid was in cases of meningitis of considerable value as denoting the tuberculous origin of the affection.

Mr. **ARTHUR H. BENSON** and Dr. W. **LANGFORD SYMES** showed a Tumour removed from the Apex of the Orbit of a woman, aged 48 years. Three and a half years previously she had received a blow in the eye from the head of a calf which she was feeding. Two months after the injury the sight began to fail and at the time of the operation vision was wholly gone from atrophy of the optic nerve. The eye was proptosed and very defective in motion. The growth, which entirely surrounded the nerve, occupied the entire apex of the orbit and the globe sat in a depression on its anterior surface, but was quite free from attachment to it in any place. The very slow growth of the tumour and its very slight malignancy were remarkable, but the point of greatest clinical interest was the loud respiratory bruit which could be heard with a stethoscope placed over the globe, both inspiration and expiration being easily heard. The bruit was also to be heard, though to a much less degree, over the sound eye. There was no vascular bruit to be heard. Since the removal of the tumour nearly four months ago there has, according to the patient's account, been no recurrence and she wears an artificial eye. Dr. Symes found the tumour to belong apparently to the sarcomata but with a peculiar locular or alveolar arrangement.

The **PRESIDENT** exhibited a Brain with Small Aneurysms on Various Cerebral Arteries.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 13th, Dr. Joseph Groves, the President, being in the chair.—Dr. Sidney Davies (medical officer of health of Woolwich) read a paper on the Sources of Infection in Tuberculosis based on an examination into 50 deaths of children under ten years of age certified as due to tuberculosis or meningitis, and 173 notified cases of phthisis in his district from July, 1902, to June, 1903, and the Registrar General's annual summaries. Of the 50 deaths of children 13 were due to simple meningitis and 37 to tuberculosis, and from a table showing the history, surroundings, &c., of the tuberculous cases it appeared that in 31 the infection could be certainly or probably traced to some member of the family or household, and in two to the milk, while in four the cause remained unknown. As regards adults the question was beset with difficulties owing to the insidious onset, the slow and uncertain progress of the disease, and the possibility of an indefinite number of successive exposures to infection, some of which the individual might resist while succumbing to others. After classifying his cases according to age, sex, and the localisation of the lesion he remarked that the Registrar General had contrasted the great reduction, amounting to 50 per cent. during the past ten years, in the mortality from peritoneal tubercle with the much smaller decline in the deaths from tuberculous meningitis which closely followed the general mortality from phthisis. The former decline was most marked in London and district where the milk-supply had been brought to a greater or less extent under municipal control and afforded strong evidence of the connexion between abdominal tuberculosis and an in[illegible] l infection took place in t[illegible] e public-h use, and the [illegible] were infected in the home only, while the probable sources among the adults in his tables were—home, males 14, females 11; workshops, males 27, females two; public-houses, males 40, females three; and undetermined, males 48, females 28. The workshops, however, of the Royal Arsenal were so lofty and spacious as well as suitably ventilated as to approximate to work in the open air. As to the public house there were two factors to be considered, the saturation of the sawdust-sprinkled floors with expectoration, more or less of it always that of consumptives who often passed hours there when unable to work, and the tendency of alcoholic excess to induce tuberculosis, from which, indeed, the majority of habitual drunkards ultimately died and which accounted for the extraordinary mortality among barmen, though in their case due perhaps rather to their constant exposure to infection, especially when sweeping the floors. Brouardel had insisted strongly on this connexion between alcohol and tuberculosis, which was confirmed by the returns of the Registrar General.—Dr. A. Newsholme described the steps being taken in Brighton to minimise the danger of infection in the public-house but expressed his belief that there were far greater dangers in the workshop than Dr. Davies seemed to think and urged the necessity for damp and dustless cleaning. It was, however, in sanatoriums only that the precautions could be satisfactorily taught. Tuberculosis from milk was not always or necessarily mesenteric but might be first manifested in the lungs, as Nocard had shown glanders to be even when introduced directly into the stomach.—Dr. F. J. Allan agreed as to the great danger of spitting in workshops but considered that it was scarcely less in warehouses and offices. With children it was not easy to distinguish between simple and tuberculous meningitis and the latter might be through tonsillary infection with dust as likely as with milk.—Dr. E. F. Willoughby referred to Brouardel's classical instance of 23 clerks in one office succumbing to tuberculosis in 11 years after the disease had been introduced by one of them but fresh cases ceasing to appear after he had spittoons provided and the rough floor planed and waxed and mopped with damp cloths instead of being dry-swept and the air full of dust when the clerks entered in the morning.—Mr. G. Milson supported from his own experience the remarks of Dr. Newsholme and Dr. Allan, and Mr. Shirley F. Murphy spoke as to the question of milk control and boiling. The reduced phthisis among women might, he thought, be partly due to better living through the cheapening of the chief articles of food.—Dr. F. G. Crookshank asked for an explanation of the fact that 25 per cent. of the deaths in lunatic asylums were due to phthisis, though the dements who formed the majority of cases rarely expectorated at all. The lungs were, however, by no means constantly the primary seat of infection as was commonly supposed, for most necropsies on acute cases at the Hospital for Consumption and Diseases of the Chest at Brompton pointed to the mesenteric glands being first involved.—Dr. Symons wished that such investigations could be carried out by medical officers everywhere on uniform lines. Nowhere had there been such a reduction of overcrowding and at the same time of phthisis as at Bath, and Dr. Christopher Childs referred to the experiments of Cornet and others as to the infectiveness of cough spray and of coughing and loud speaking as means of diffusing infection.

Pathological Society of Manchester—A meeting of this society was held on Nov. 11th, Dr. E. S. Reynolds, the President, being in the chair.—Dr. R. T. Williamson showed specimens of the Brain from a case of Intense and Persistent Headache. Paralytic symptoms and optic neuritis were absent. There were no signs of disease of the thoracic or abdominal organs and the urine was normal. The necropsy revealed dilatation of all the ventricles of the brain with fluid; no tumour or abscess was present. Dr. Williamson also showed microscopical and macroscopical specimens of a Brain Tumour in the White Matter of the Cerebral Hemisphere (centrum ovale) The symptoms were those of hemiplegia of gradual onset and finally motor aphasia and word deafness. Headache and vomiting were absent at first; no optic neuritis was present at a late period of the illness. The growth consisted of a connective-tissue stroma in which were imbedded tubules and small cyst-like cavities lined with cylindrical epithelial cells closely resembling those lining the central canal of the spinal cord and the primitive neural tube of the embryo.—Dr. R. G. Rows gave a lantern demonstration of Cavities in the Cord of Vascular Origin. In the first case there was an extreme degree of hyaline degeneration of the walls of the vessels, which not only interfered with the flow of blood but also obstructed to a large extent the chief lymph paths of the spinal cord—viz , the perivascular sheaths in which there are no walled lymphatic vessels but the lymph flows through its interstitial spaces in an ascending stream. A chronic œdema was thus produced which led to the formation of cavities around the vessels by distending the interstitial spaces of these sheaths and by causing an atrophy of the nervous and neuroglial structures by interfering with their nutrition. In the second case micrococci were found in the posterior root ganglia and there was an acute vascular change following the toxic infection, which in some places had led to rupture and hæmorrhage and in others to the formation of cavities around the vessels by an acute œdema, which again had distended the interstitial spaces of the perivascular sheaths. In neither of these cases was there any sign of proliferation of the neuroglia, owing in the first case to malnutrition and in the second case to a paralysing, by the toxins, of its power of reacting to an irritant. In a third case similar cavities were seen in the cortex and white matter of the brain of a girl who had died in the condition of status epilepticus.—Dr. I. Walker Hall communicated the results of a research on the Purin Bodies of the Fæces. He found that with small and medium quantities of purin bodies in the food there was no increase in the amount of purin bodies excreted. When large quantities of foods rich in purin were taken or purin bodies themselves were ingested the fæcal purins were augmented. Hypoxanthin and xanthin were well absorbed but guanin and adenin were to a great extent excreted. There was, however, a distinct personal factor in regard to the absorption of the purin bodies.

Forfarshire Medical Association.—A meeting of this society was held on Nov. 5th, Dr W. Graham Campbell, Vice-President, being in the chair.—Mr. D. M Greig showed a patient five months after excision of the entire rectum and part of the sigmoid flexure by the trans-sacral route for Epithelioma. The patient was a man, about 37 years of age, who had had symptoms for about a year before operation. The result was very satisfactory and it was pointed out how much better and more comfortable this patient was with an artificial anus in the upper angle of the sacral wound than he could have been with the artificial opening in the iliac or lumbar regions.—Dr. W. E Foggie showed three patients (two in one family) suffering from Pseudo hypertrophic Paralysis. In one patient there was a marked enlargement of the tongue and in addition there was some hypertrophy of the lower lip that was suggestive of commencing facial involvement. It thus formed one of those transition cases that were used by Erb in his argument for the inclusion of all forms of idiopathic degeneration under one common clinical name—progressive muscular dystrophy. As regards treatment any good that had been obtained had resulted from systematic muscular exercises.—Dr. J. Mackie Whyte demonstrated Kronig's method of percussing the apices of the lungs on a patient on whom he also showed Litten's sign. Several diagrams were shown of this method of percussion in diseased chests.—Dr. C. McVicar showed a female patient, aged 61 years, nine months after excision of the right knee-joint with firm union. He described the disease as having been very advanced, affecting ligaments, cartilage, and bone. Firm union was not obtained until four months' rest in bed after the operation and now the patient was free from pain and able to walk with ease. Comment was made on the firm union resulting in a patient of such advanced age and with this result he compared those obtained in old persons who had come under his care for intracapsular fracture of the neck of the femur. In one case he obtained bony union only after seven months' treatment. He showed two specimens obtained post mortem from similar cases which showed no attempt at bony union, in one after being seven years in bed. He also showed a specimen of similar fracture which occurred in a man, aged 82 years, who died a month later. Post mortem recent hæmorrhages were found in the neighbourhood of the joint but no callus formation was present. He thought that these cases illustrated the utter futility of treatment by splints of intracapsular fractures of the neck of the femur in old people probably due to the difficulty in steadying the upper fragment. These patients should simply be made comfortable for a month or so and if able for operation the head of the femur might then be excised.—Mr. Greig considered that excision of the head of the femur was accompanied by such an amount of shock as usually to contra-indicate interference in old people.

Dermatological Society of London.—A meeting of this society was held on Nov. 11th, Dr. T. Colcott Fox being in the chair.—Dr. J. H. Sequeira showed: 1. A woman, aged 56 years, with Multiple Rodent Ulcers on the Face. The history was that 30 years ago she had had under the left eye a growth diagnosed as a molluscum and of the size of a pea. This was excised and afterwards cauterised many times but it had grown until at the age of 44 years it gradually died away. Ten or 12 years ago another sore appeared in the neighbourhood of the left eye which had spread and broken down into an ulcer during the last three or four months. There were at the time of exhibition another large ulcer on the nose of 12 months' duration, another on the right upper eyelid of two months' duration, an ulcer on the chin, and others on the right cheek, all of about ten months' duration. There was also a papillomatous condition round the alæ nasi from which the patient averred the ulcers always developed. The case was interesting on account of the extreme rapidity of spread as well as on account of the multiplicity of the growths. 2. A man, aged 58 years, showing a very good example of Lichen Planus in which the individual papules spread centrifugally so as to form rings. The eruption was first noticed 15 months previously and affected the arms and the legs.—Dr. A. Whitfield showed a man who had for two years at least been affected with Typical Lymphadenoma. In June, 1903, he had begun to develop itchy papules over the arms, the buttocks, and the legs. There was also a large patch of pigmented scarring where similar papules had been on the right breast. The newest lesions appeared to be urticate in nature and these on subsiding left hard infiltrated papules and finally insignificant scars. The diagnosis offered was pseudo-leukæmic prurigo and this was accepted by all the members.—Dr. E. G. Graham Little showed: 1. A case of Prurigo

(Hebra) in a youth. aged 19 years, the eruption having begun only one year previously and the mother being certain that he had had no previous skin eruption. 2. A case of Dermatitis Herpetiformis in a woman who was six months pregnant and in whom the eruption had existed for four weeks. The history showed that she had had a previous attack three days after her last delivery. 3 A girl, aged 17 years, with a very typical eruption of the small Follicular Syphilide all over the back and the limbs but especially over the gluteal regions.—Dr. J. M. H. MacLeod showed a male infant, aged 11 months, who had been affected with Grouped Comedones of the Chest since his seventh month. The lesions were very numerous and developed into red papules and then into pustules, finally leaving a little scarring on resolution. No local application had been made to the chest in the way of a liniment since birth.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Nov. 6th, Dr. P. McBride, the President, being in the chair.—Sir Felix Semon, in opening a discussion on the After-treatment of Intranasal Operations, said that he should limit his remarks strictly to intranasal operations, entirely excluding those performed for disease of the accessory and naso-pharyngeal cavities. Local anæsthesia, such as the use of cocaine, was to be preferred to general anæsthesia in the great majority of operations as it was essential for the patient to be sitting upright so that the operator might see clearly. With regard to adrenalin he was under the impression that since he had used it he had heard more frequently from patients of the occurrence and persistence of hæmorrhage than in previous times. For the prevention of adhesions the advantages and disadvantages of plugging were referred to, the opinion being expressed that plugging was apt to produce considerable irritation, to cause local anæmia of the injured parts, and thereby to prevent healing With the view of diminishing (though it did not actually prevent) inflammatory reaction, a spray consisting of three grains of cocaine and half a drachm of boric acid in six ounces of water was recommended to be used three times daily. For the prevention of secondary hæmorrhage firm plugging should be avoided, as it did not with certainty prevent it, as such hæmorrhages might, and often did, occur when the tampon was removed on the day after operation., If there were no reason to expect considerable hæmorrhage he used no plugging but ordered the boric acid and cocaine spray previously indicated. If the wound were at all extensive a strip of cyanide gauze soaked in a solution of hydrogen peroxide was introduced with the view of preventing subsequent hæmorrhage. If bleeding occurred the patient should be directed to apply cold-water compresses over the nose. The advice that the patient should inspire deeply with closed mouth and slightly expire with open mouth would also be found very useful. In some cases, of course, powerful styptics and energetic plugging by means of Belloc's cannula were indispensable. Meddlesome interference, such as washing out, cauterising of granulations, insufflations, and similar procedures, was deprecated as being usually superfluous and sometimes even prejudicial to healing. If there were risk of the formation of adhesions the cicatricial bands should be divided by cutting instruments (not with a probe) and a piece of gutta-percha paper should be introduced into the nose.—Mr. H. T. Butlin, Dr. R. H. Scanes Spicer, Dr. StClair Thomson, Mr. E. Cresswell Baber, and others took part in the discussion.

HUNTERIAN SOCIETY.—A meeting of this society was held on Nov. 11th, Dr. F. J. Smith being in the chair.—Mr. Harold L. Barnard opened a discussion on Appendicectomy. He thought that the great dangers to be [illegible] before the appendix was divided. Catgut was preferable to silk and he particularly deprecated the use of large silk. Appendicectomy might be performed either as an interim operation or during the acute attack. In the former case he objected to deferring the operation until after the second attack as acquiescing in a mortality of from 10 to 30 per cent. of all cases; operation after the first attack was the practical rule and saved from 7 to 10 per cent. of the patients; operation after one attack of appendicular colic was the ideal operation and would save nearly the total mortality. When appendicectomy was performed during the acute attack Mr. Barnard advocated it in the first 24 hours of the first attack, but he was not so confident that it should be done in the first 24 hours of second or third attacks, for [illegible] were less. I[illegible] be avoided [illegible] any prolonged search for the appendix. In general peritonitis, since the damage was already done, he did not think that it mattered much whether the appendix were removed or not.—Mr. James Berry pointed out how important it was to avoid section of nerves in abdominal incisions since this led to atrophy of muscle and consequent ventral hernia. He thought that fine silk possessed many advantages over catgut and few disadvantages.—Dr Ernst Michels advocated making the incision through the sheath of the rectus. He remarked that patients liable to appendicular colic often improved in health after removal of the appendix.—Mr. G. L. Cheatle, Dr. W. H B. Brook (Lincoln), Mr. Hugh M. Rigby, and others also discussed the paper.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society was held in the Medical Library of University College Bristol on Nov. 11th, Mr. J. Paul Bush, being in the chair.—Mr. T. Carwardine showed specimens of Mammæ in Ovarian Dermoid and a Prostate removed by the suprapubic method.—Dr. E. W. H Groves, Dr. P. Watson Williams, Mr. C A. Morton, and Mr. W. Roger Williams remarked on the specimens.—Dr. J. O. Symes showed microscopic specimens of Trypanosomes in human blood.—Dr. E M. Skerritt and Dr. F. H. Edgeworth spoke on the specimens.—Mr. A. W. Prichard read a paper on the Subsequent History of a case of Pylorectomy and showed specimens.—The President, Mr. Morton, Mr. Carwardine, Mr. Roger Williams, and Mr. G. Munro Smith remarked on the case.—Dr. J. Michell Clarke read an account of a case of Hereditary Syphilis and showed microscopic specimens from the spinal cord which was affected [illegible] consecutive degeneration of [illegible]ts; also of a case of Glioma [illegible] the cord of whom was found a cavity (hydromyelia) in the lower cervical region.—Dr. Walter C. Swayne read a paper on a case of Cæsarean Section.—Mr. Roger Williams read a short paper on Subungual Exostosis.—Dr. J. L. Firth remarked on the paper.

PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW.—A meeting of this society was held on Nov. 11th, Mr. A E. Maylard, the President, being in the chair.—Dr. Donald Fraser discussed a case in which Cerebral Hæmorrhage occurred in a patient who had been recently operated on for appendicitis. Before the operation he had shown symptoms of cerebral disturbance amounting almost to mania. Eventually he was sent into a lunatic asylum. The condition was regarded as of septic origin—thrombosis followed by hæmorrhage. The region of the brain principally affected was the frontal lobes.—Dr. James Hamilton read notes of a case of Hydronephrosis in a young man. The specimens were demonstrated by Dr. John Anderson.—Dr. W. B. Inglis Pollock read a paper on Tuberculous Iritis and demonstrated specimens.—Dr. J. M Munro Kerr demonstrated a specimen of Retroperitoneal Dermoid Tumour removed by Vaginal Cœliotomy. It was a thin-walled cyst with the usual contents of a dermoid. It lay behind the peritoneum but in front of the rectum and quite free from it. The uterus, the ovaries, and the Fallopian tubes were normal.—A large exhibit of microscopic and naked-eye specimens and skiagrams was also on view during the meeting.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 6th, Dr. R. E. Scholefield, the President, being in the chair.—Mr. G. Bellingham Smith read a paper on Menstrual Pain. He said that from the point of view of treatment cases might be divided into two main classes—namely, those in which the pain preceded by some days the menstrual flow and those in which the pain occurred about the time of onset of the flow. The cases that would not be benefited by division or dilatation of the cervix fell under the first heading, while those which would derive benefit from this operation came within the second class. In cases where other measures gave no relief, the ovaries not being diseased, and it was deemed advisable to perform oöphorectomy, then removal of one ovary was useless even if the pain were on that side alone, as after removal of that ovary the pain would go to the other. He mentioned a case where after removal of both ovaries the patient returned to ask for the right kidney to be taken away as the pain was as bad there as it had formerly been in the ovaries.—The President, Dr. T. O. Meggison, and Dr. J. H. Keay discussed the paper.

FOLKESTONE MEDICAL SOCIETY.—A meeting of this society was held on Nov. 6th at the Victoria Hospital.—The President (Dr. T. Eastes) showed a case of Ankylosis of the Elbow-joint; Mr. A. Wylie a case of Post-hemiplegic Chorea in a young child; Mr. W. F. Chambers a case of Gumma of the Hand; Mr. W. W. Linington a case of Tabes Dorsalis in a man, aged 27 years; and Dr. W. J. Tyson two cases of Congenital Cataract in patients 16 and 18 years of age respectively.—Dr P. G. Lewis read notes and showed a specimen of Embolism of the Superior Mesenteric Artery of a woman, aged 46 years, in whom 20 inches of the small intestines had been affected. The aorta at the origin of the superior mesenteric artery showed a localised ulcerated surface of the lining membrane. The remaining part of the aorta was normal.

Reviews and Notices of Books.

Disease of the Pancreas: its Cause and Nature. By EUGENE L. OPIE, M.D., Associate in Pathology in the Johns Hopkins University. London and Philadelphia: J. B. Lippincott Company. 1903. Pp. 359. Price $3.

THIS work is written mainly from the point of view of etiology and pathology and the clinical aspect is only lightly touched upon. Few conditions present greater difficulties of diagnosis than the various forms of pancreatic disease; but with an increased knowledge of their etiology, their nature, and their relation to other diseases, doubtless their recognition will be facilitated.

The etiology of pancreatic diseases presents problems which have long remained unexplained. This is partly due to the fact that lesions of the organ seldom occur as primary or isolated conditions but are usually consequent upon changes in the duodenum, the liver, or the bile passages. Dr. Opie brings evidence to show that both acute hæmorrhagic pancreatitis and chronic interstitial inflammation may be produced by biliary calculi. Pathological changes in the gland have emphasised the importance of certain gross anatomical and histological features and for this reason especial stress has been laid on the normal structure of the organ. The chapter devoted to the Anatomy of the Pancreas and its Variations is consequently a long one. It is shown that the pancreas is subject to greater variation in size and shape than are other important glandular organs—for example, the ducts of the gland vary widely in their conformation and in their relation to one another and to the common bile duct. Diagrams are given demonstrating the varying relations of the duct of Santorini to the duct of Wirsung and by means of which the differences in the arrangement of the anastomosis of the ducts are clearly shown.

In the chapter upon Histology attention is directed to the islands of Langerhans. Dr. Opie has himself made a close study of these bodies and maintains that certain facts may be considered to be established. He finds that these "islands" are composed of cells of epithelial type, having the same origin as those which form the acini. Ramifications of the pancreatic duct do not penetrate the interacinar islands, while, on the other hand, these bodies have an intimate relation to the vascular system. The function of these structures has been the subject of some speculation and strong evidence has been afforded that the islands of Langerhans control the assimilation of sugar.

Dr. Opie has devoted a whole chapter to the discussion of the relation of diabetes mellitus to lesions of the pancreas. After an interesting criticism and examination of the work accomplished by various observers he thinks that it has been proved that in considerably more than half of all cases diabetes is the result of a destructive lesion of the pancreas. Further, that when diabetes is the result of pancreatic disease injury to the islands of Langerhans is responsible for the disturbance of carbohydrate metabolism. The most common lesions which injure the islands are chronic interstitial inflammation of the interacinar type and hyaline degeneration. Chronic interstitial inflammation may be the result of general arterial sclerosis or of toxic substances—for example, alcohol causing chronic inflammation of both the liver and the pancreas. The islands of Langerhans show a special tendency to undergo hyaline degeneration but the cause of this lesion is obscure. Finally, other lesions of the pancreas do not exhibit a tendency to select the islands of Langerhans but produce diabetes because they destroy the interacinar islands along with the secreting parenchyma. These observations seem to be well founded and are of great value in the comprehension of the pathology of diabetes mellitus.

The symptoms and treatment of pancreatic disease are briefly but ably discussed. The difficulties of diagnosis are pointed out. The symptoms certainly present little that is characteristic upon superficial examination and their true origin is obscured by the involvement of other organs, notably the liver, the bile passages, and the duodenum. Dr. Opie, however, in our opinion, rather exaggerates the difficulties when he says: "Disease of the pancreas is rarely recognised during life." By careful observation of the progression of the symptoms and assemblage of physical signs a presumptive diagnosis can frequently be arrived at. Medical treatment in cases of pancreatitis can do but very little and it is only by surgical means that the seat of the disease can be reached.

This volume is well worthy of perusal and contains much that is interesting concerning pancreatic disease. Scant space is devoted to such diseases in most text-books of medicine and pathology, consequently the information contained in this work is of exceptional value.

The Nature of Man: Studies in Optimistic Philosophy. By ELIE METCHNIKOFF, Professor at the Pasteur Institute, Paris. English translation edited by P. CHALMERS MITCHELL, M.A., D.Sc. Oxon. London: William Heinemann. 1903. Pp. 302. Price 12*s.* 6*d.*

NEARLY 40 years ago Professor Tyndall scandalised the Church and society by asking the following question: "Can prayer prove itself a match for vaccination?" To-day Professor Metchnikoff, with the obvious sincerity of a seeker after truth, asks whether religion or philosophy can offer suffering humanity consolations in the least degree comparable to those which science can afford. Those who read his remarkable work entitled "The Nature of Man" and can convince themselves that his story and the message of hope which it conveys are not the vain imaginations of megalomania but the logical inferences to be drawn from observed facts may well pause for a reply. Society to-day is differently constituted from what it was some 40 years ago when Professor Tyndall startled it with his question, and presumably it will receive Professor Metchnikoff's iconoclasm in a spirit of greater tolerance. The Church, however, no less militant in the present year of grace than it was in 1866, may be expected to put on its armour and to sally forth to battle to slay this new disturber of its ancient faith. The argument which Professor Metchnikoff unfolds in a story more fascinating than the Arabian Nights is that human misery and suffering are due to disturbances in our organic equilibrium which strike discords within our mortal frame and rack our flesh with the torments of Procrustes. These disharmonies between our corporeal organisation and our environment have been forced on suffering humanity by the evolution of mind which has introduced artificial factors into the environment but which has not, so far, shown the perspicuity to adjust by corresponding artificial means the shortcomings of our organic constitution. Conscious of its own infirmities and at last unable to delude itself "with beautiful mirages offered by religions and systems of philosophy," poor humanity must now find a haven of rest in the expedients of science and still the disturbances of its organic constitution in the bosom of practical hygiene.

These studies inform us that religions and systems of philosophy have been prompted into being by the imperative fear of death. Had there been no such dread of annihilation there would have been no such need of consolation. According to the creed of Professor Metchnikoff the fear of death, which grows as old age creeps upon us, is only the prompting of an instinct which tells us that we are dying before life's span has run its natural course. According to this optimistic philosophy we are to believe that if we live our natural number of days the dread fear of death will ultimately, perhaps in many generations, pass insensibly into an "instinct of death," a welcoming of annihilation and everlasting sleep. This natural death is not of to day or perhaps of to-morrow; it must be regarded as a present "possibility rather than an actual occurrence." We die because of the imperfection of our bodies which we know not how to adjust. How then can science—this new *vis medicatrix*—save us from the disharmonies which compass our end? How can science compensate us for the religion and the philosophy which at her bidding we are to yield for evermore? Read the Metchnikoffian creed and your eyes shall be opened in understanding.

From a purely scientific point of view Professor Metchnikoff's proposed redemption of man from all his woes by the expedients of applied scientific knowledge deserves to be taken in all seriousness. He points out that in course of the phylogenetic evolution of man—an evolution, by the way, which has resulted from the "miscarriage of an ape"—he has entered into a heritage of a considerable number of rudimentary organs which in his present environment are exceedingly dangerous to him. Of these ancestral relics the appendix and the large intestine are the most discordant elements: the appendix because it is an involuting organ and endowed with retrogressing powers of resistance to disease and the large intestine because, as a barbarous relic of a herbivorous past, it harbours bacteria which increase at the rate of 180,000,000,000,000 per diem. These bacteria generate toxins which poison the nervous system and lead to the premature degeneration of its highly differentiated elements. These and many other disharmonies may be attuned to perfect peace by the expedients of modern surgery and by obeying the laws of a rational hygiene—thus will it come about that the number of our days will be those of Methuselah and we shall die a natural death and welcome its coming.

Both as a system of optimistic philosophy and as the exegesis of scientific views which are the outcome of the most brilliant biological investigations Professor Metchnikoff's studies invite criticism as they demand attention. The "instinct of death," that welcoming of annihilation which in his profound optimism Professor Metchnikoff believes will awaken from its thousand years of slumber and cheer us on our bed of natural death, is a large conception. "This instinct," continues Professor Metchnikoff, "lies deep in the roots of the human constitution. Will the means be found to bring it to the surface? Has not the enormous period during which it has remained latent led to atrophy? The science of the future alone can answer that question But the persistence of organs and structures that are extremely ancient gives us the hope that the instinct of natural death may emerge from its latent condition when old age has become a normal process." But will it? Instinct of this kind is eminently a primitive form of cerebration, from the ashes of which higher mental attributes have been developed in man. If judgment, memory, and receptivity are qualities of a high grade of mental evolution it must be degeneration and not evolution which will give us back the primitive instinct of some ancestral ape.

It has been said that most great investigators in pathology come in their old age to refer the ultimate causes of human disease to the nervous system. Professor Metchnikoff has not reached that stage yet, he leaves off where he began with the phagocyte: the phagocyte is the master as well as the servant of man. His explanation of hair growing white and brain cells degenerating through the agency of "microphages" is hardly an explanation of the essential degenerative process but it is an extremely brilliant scientific observation.

The translation of "The Nature of Man" has been conducted by Dr. Chalmers Mitchell with the utmost skill and with much literary *finesse*. In a work which deals largely with sexual questions, in which, as Dr. Mitchell says, "there is much plain speaking on matters that modern civilisation attempts to conceal," and which will be read by educated people of both sexes, any want of taste or looseness of expression might easily give offence. Dr. Mitchell is not only to be congratulated on his courage in translating this volume but also on the elegance and the refinement of the language by which he has enabled Professor Metchnikoff to present his philosophic conceptions to the English-speaking peoples.

Essentials of Pelvic Diagnosis with Illustrative Cases. By E. STANMORE BISHOP, F.R.C.S. Eng. With an Appendix on Examination of the Blood, by C. H. MELLAND, M.D., M.R.C.P. Lond. Bristol: John Wright and Co. 1903. Pp. 297. Price 9*s*. 6*d*. net.

IN his preface to this work Mr. Stanmore Bishop points out that the art of diagnosis is usually taught in the ordinary text-books of medicine on the inductive principle. As he says, this is the very reverse of the conditions met with in actual practice. At the bedside the symptoms are known, the disease is not The latter has to be deduced from the presence or absence of certain signs or symptoms. This work is an attempt to render the mental processes necessary in such a deduction easier to the student. Starting with readily observed symptoms or physical signs the differences between various classes of cases in which they are equally present are pointed out; these classes are again divided into groups in the same way; the groups once more into sections, and these in their turn are split up by means of definite variations in the symptoms until the desired diagnosis is arrived at. The main features of the book are a series of numbered paragraphs entitled "Lines of Diagnosis" in which the general dividing symptoms are called attention to. These are followed by a series of diagnostic tables in which a more detailed view is taken of the entire class, group, or section of pathological conditions to which the case belongs. As the work is concerned with the diagnosis of pelvic conditions alone, only such cases as can be classed under this heading are considered, but those occurring in the male sex as well as in the female sex are included.

The book is divided into five parts. The first of these is devoted to methods of diagnosis. In practising bimanual examination of the pelvis with the patient on the left side the author recommends the use of the left hand internally, while the right hand is to be passed between the thighs and placed flat upon the abdomen with the fingers pointing towards the umbilicus. He thinks that in this way a better appreciation of the relations of the various pelvic organs can be obtained. In the second and third parts of the book, devoted to the lines and tables of diagnosis referred to above, all the diseases of the pelvic organs are considered under their different symptoms. A series of ten cases is given with details to show the best manner of using these tables and there is an appendix devoted to a description of the methods of examining the blood and the methods of staining the tubercle bacillus and the gonococcus. The difficulties of writing such a book are obvious but the author may be said to have overcome them in a most admirable manner.

The volume should be of considerable value not only to students but also to teachers in refreshing their memories as to the inability of students to differentiate between many conditions which to them appear most dissimilar in the light of their greater clinical experience. There is an excellent index with numerous cross references.

La Russie d'Europe: The General Hygiene of European Russia. By Dr. A. BONMARRIAGE, Delegate of the Belgian Government to the Moscow International Congress of Medicine. With numerous Maps and Illustrations. Brussels: Spineux and Cie. Paris: Le Soudier. 1903. Pp 547. Price 20 francs.

THIS is undoubtedly one of the greatest works on Russia that has ever been published. It is not a history, it is not a story, it is not a book to be taken and read straight through. It is more like a State document and indeed has been written with all the help the State could give. Consequently it does not contain a word of politics, barely any criticism, and in parts is as dry reading as any Blue-Book. But, like Blue Books, it is an extremely useful publication and could be referred to with great advantage by anyone meditating a journey to Russia or intending to take part in any enterprise or business in that country. The work gives systematically an exhaustive account of all the leading material factors that contribute to constitute the Russian empire not as a political institution but as a geographical fact. It is divided into chapters according to the main facts; thus the first chapter gives the situation, form, and size of European Russia. Then we have the *relievo*, that is the mountains and plains, and this is followed by the study of the soil or geology, and this naturally leads up to the water-courses. The northern slope to the Arctic Sea, the western slope to the Baltic, and the southern slope to the Black Sea and the Caspian Sea are very fully described. The mountains, the water-courses, and the soil determine the vegetation and influence the climate and they in their turn attract settlers and draw together vast populations; but the latter, by interfering with the natural growths, alter the climate and the sanitary conditions. In time these changes bring about other modifications in the populations. Thus the difficulties of communications have converted the great rivers into the national highways, but as towns have sprung up on their banks the rivers have been all the more liable to contamination as in many cases the current is very slow, for the countries traversed are sometimes almost level. Sanitation, therefore, especially in regard to the prevention of the pollution of rivers, is a matter of especial importance in Russia. Then as the population spreads inland, away from the sea and the great river courses, the tendency is to cut down the woods, to burn the logs, to export them, or to build houses with them. But as the forests disappear the climate is disadvantageously modified, and even in Russia the cry is now that new forests should be planted. And who are the people who thus play fast and loose with nature at the risk of losing their means of existence by such ignorant action? We find in the work before us a most elaborate ethnographical study, with many illustrations of the various types of humanity that people the Russian empire. But the leading races are undoubtedly the Slavs, the Finns, the Tartars, and the Mongols. The Finns are probably the aborigines. The Slavs come from the southern Alpine districts of Europe, they belong to the Aryan race and constitute the Great Russians of Central Russia. They are the dominating and most civilised race, mixing with, permeating, and modifying the Asiatic Mongol and Tartar. But this natural evolution is being considerably modified by the development of industries and of railways. In 1856 the industrial production of the empire only amounted to 200,000,000 roubles; in 1897 it was estimated at 2,950,000,000 roubles. The number of artisans has increased fourfold. Yet even to day there is not a province in Russia where less than 80 per cent of the population are employed in agriculture. All these facts are admirably set forth and they are rendered more clear by a series of maps There are coloured maps for temperature, rainfall, soil, the distribution of races, and so on. Then a very complete index enables easy reference to any phase of the subject.

Dr. Bonmarriage is strongly of opinion that man is the slave of his surroundings and thus describes his own work. "The ideal for the civilised man consists in utilising all the resources which nature offers him and this wherever he may be To succeed in such effort he must first of all realise what are the advantages and the inconveniences of the climate, what are the crops the soil can produce, what are the various products that can be cultivated, what is the water régime of the country, and what is the value and degree of civilisation of the natives. When he is well acquainted with these various elements he will realise that he has not paid too dear for the experience acquired. He will find it more easy to put himself in harmony with the centre in which he has to live. It is for this purpose that we have summarised and described the natural elements of European Russia which more especially interest the hygienist."

LIBRARY TABLE.

A Text-book of Organic Chemistry. By Dr. A. F. HOLLEMAN, Professor Ordinarius in the University of Groningen, Netherlands. Translated from the second Dutch edition by A. GAMIESON WALKER, Ph.D., B A., assisted by O. N. E MOTT, Ph D. London: Chapman and Hall 1903. Pp. 572. Price $2 50—This book, originally a Dutch publication, has been translated by an English chemist and issued by a firm of New York publishers for whom Messrs. Chapman and Hall are agents in London Dr. Holleman has written, it is obvious, a work of distinct educational value and instead of burdening the student with an overwhelming number of disjointed facts he adopts the preferable course of describing the general principles which underlie the structure of organic compounds We say the preferable course assuming that students already possess a general knowledge of chemical principles. We do not agree that the discussion of the constitution of organic compounds is suitable for a beginner. According to our view a certain number of facts should be discussed first and a laboratory course is also helpful. Dr. Holleman is certainly at his best when dealing with theoretical considerations, although it is true that in this volume he has included a description of certain technical processes which relate to the output of organic bodies There is no chapter on testing and even in the account of alkaloids no description is supplied of the colour reactions which serve to identify them. Only a short paragraph is given dealing with the general principle by which alkaloids may be separated and identified. No modern work would be complete without a reference to the theory of ions and electrolytic dissociation, but we are bound to admit that this interesting development as it relates to organic chemistry is dismissed somewhat summarily. However, we notice that the corresponding work by the same author on inorganic chemistry is referred to as containing a full explanation of the subject. The term "halide" as applied to an iodide, bromide, or chloride will be new to many readers. We like the plan of the book; it is written in excellent sequence as regards theory and the structure of compounds and should prove to be an excellent companion to the student attending his first course of organic chemistry.

A Short Manual of Analytical Chemistry. By JOHN NUTER, Ph.D., F.I.C., F.C.S. Ninth edition, illustrated. London: Baillière, Tindall, and Cox. 1903. Pp 235. Price 6s.—Although this work is written within the limits of a special course of instruction, yet we think it will be useful to the general student of analytical chemistry. The author has had considerable laboratory experience and the sections bear evidence of his familiarity with the details of both qualitative and quantitative analysis. Special attention is given to the requirements of pharmaceutical students. Necessarily brief as are some of the details in regard to the analysis of foods, drugs, and pathological products, yet they serve to prepare the student for a more exhaustive account of the subject. The author has certainly succeeded in compressing a good deal of material essential to the general student of chemistry in comparatively small compass. To the class of student described the work should prove of undoubted assistance.

Mr. Woodhouse's Correspondence. By G. R. and E. S. London: Methuen and Co. 1903. Pp. 277. Price 6s.—This book is indeed "infinite riches in a little room," it is a picture of types exquisitely finished and mostly disagreeable. Mr. Algernon Wentworth-Woodhouse is a widower, eminently selfish, rich, and scrupulously polite. Elaine Thompson, his god-daughter, to whom Mr. Woodhouse with unkind truth writes, "If my memory does not deceive me you were christened Ellen," is also charmingly selfish and has written a work called the Woof-Warp. Elaine's end, however, is sad, for she finishes her career, in the book at least, by accepting a post under a food depôt to write attractive advertisements. From our own medical point of view, however, the most attractive character is Lady Louisa Fitzwigan who in company with her medical advisers is a perfectly delightful character. Dr. Riley, the honest practitioner, and Dr. Chubb, the—well, we will call him the fashionable one, are contrasted types and by no means overdrawn. Here is Dr. Chubb's muffin diet which, as Lady Lousia says, was "invented by him and is, I hear, making his fame. The patient takes a hot buttered muffin every two hours and sips a tumbler of tepid water 60 minutes after eating it. The results *for delicate digestions* are incredible." G. R. and E. S. are to be congratulated upon a most finished piece of work, the reading of which will give anybody half-an hour's unalloyed enjoyment.

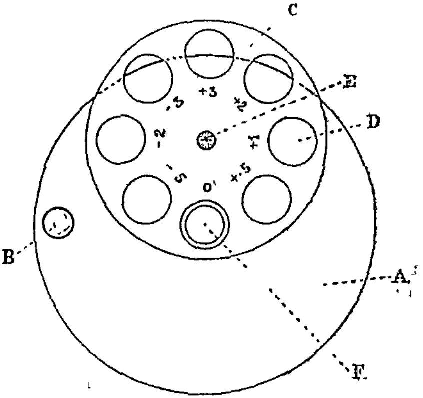
JOURNALS AND MAGAZINES.

The Practitioner.—The November number of this journal deals largely with subjects of gynæcological interest. Mr. Alban H. G. Doran contributes an article on the present position of our knowledge with regard to the treatment of uterine fibroids which is more remarkable for its comprehensive survey of rival recommendations than for any decisive conclusions as to the course to be adopted in dealing with fibromyomata in their very various degrees of harmfulness. Mr. Doran does, however, speak strongly of the necessity for keeping even quite innocuous fibroids under observation and here all will agree with him, whether they are keen advocates for early operation in most cases or not. Dr. Thomas J. Horder writes on the treatment of nephritis and devotes his attention particularly to the views and researches of Professor van Noorden. Some time-honoured plans of dieting the subjects of nephritis certainly seem to be overthrown by the most recent pathological and physiological investigations bearing on the matter. Substantial clinical support of the newer recommendations is still, however, lacking and will, we hope, be earnestly sought.

New Inventions.

A MODIFIED LARYNGOSCOPIC MIRROR.

FOR those who suffer from myopia, and more especially from hypermetropia, I venture to hope that the following addition to the forehead mirror of the laryngoscope may be found useful. *This addition consists of a circular metal* plate carrying various plus and minus lenses riveted to the metal back of the forehead mirror in such a manner that any required lens can be brought into position behind the aperture (vide diagram). This apparatus will be found much more satisfactory than the method of wearing eye-glasses and having the mirror in the centre of the forehead. The instrument which I have was specially made to my own specifications by *Messrs Archibald Young and Sons, Forrest-road*, Edinburgh.



A. The bac[illegible] laryngoscopic forehead mirror. B, Knob f[illegible] head band. [illegible] the back of [illegible] ted so that [illegible] the forehead mirror. E, Rivet fixing metal plate to the metal back of the forehead mirror. F, Inner circle represents the aperture in the forehead mirror, the outer circle represents the aperture in the metal plate, in this case carrying no lens.

IAN STRUTHERS STEWART, M B., Ch B. Edin.
Nordrach on Dee, Banchory, N.B.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual general meeting and dinner of this society were held on Nov. 10th. Mr. Joseph Smith was re elected President, Dr. G. Danford Thomas, Mr. T. Martin, and Dr. Herbert Snow were elected Vice Presidents, Mr. J Brindley James was elected honorary treasurer, and Dr. W. G Dickinson honorary secretary. At the subsequent dinner the toast of "The Society" was proposed by Mr. W. Gibson Bott and responded to by the President. Mr. H. Nelson Hardy proposed "The Officers of the Society" and urged the importance of bringing pressure to bear on Members of Parliament and others in order to promote the just claims of the Members of the College. Dr. Danford Thomas, Mr. Martin, and the secretary replied. *During the evening Mr. Sidney Gandy* gave an entertainment and the President and others contributed music.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 21, 1903.

The Relation of the Anæsthetist to the Patient and to the Surgeon.

THERE will be found in another column a letter dealing with the question of the relation of the anæsthetist to the patient and to the surgeon. The contents of this communication no less than the author's *nom de plume* show it to be written frankly from the point of view of the anæsthetist, but the points touched upon are of importance to the whole medical profession and to the public. Force is given to "Anæsthetist's" views not only by the reasonable language in which he calls attention to a state of affairs that in some circumstances may constitute a public danger, but by the fact that in a recent paper which Dr. ORMOND GOLDAN of New York has contributed to our contemporary the *New York Medical Journal* a strong plea is advanced in favour of a fuller recognition of the status and professional claims of the anæsthetist. Clearly "Anæsthetist's" attitude is not without its defenders in the medical centres of the United States. Dr. GOLDAN, writing from a ripe experience of anæsthetics both from the standpoint of an expert and from that of a careful and accurate observer of the physiological actions of the agents which his skill empowers him to employ, urges that the skilled anæsthetist is able to approach immeasurably nearer than the inexperienced to the ideal of "a featureless narcosis ending with immediate return to consciousness and absence of after-effects, both immediate and remote." He further contends that the knowledge and experience of the expert enable him to select and to apply the chosen anæsthetic by such methods and with such skill as must in many cases preserve the life of the patient. In such circumstances we are asked, Is it right or reasonable that the expert anæsthetist should have no relation to the patient other than the negative one involved in his admission to the operation as an assistant to the surgeon? Dr. GOLDAN says: "I am firmly convinced that not until the anæsthetist is fully recognised by all concerned as entirely separate from the surgeon will anæsthesia ever advance."

With the truism urged by Dr. GOLDAN and implied by "Anæsthetist" that the skilled anæsthetist is of paramount importance in certain operations we are, of course, in accord, but when we come to consider any suggestions for alteration in the status of the anæsthetist as regards the patient, the operating surgeon, or both we see that the matter requires thought. We gather that Dr. GOLDAN desires that the anæsthetist selected should attend the patient upon the same basis as would a physician, if it were deemed desirable by the surgeon that he should meet such a colleague in consultation upon the case. Dr. GOLDAN finds it possible to maintain this position in his own practice. The patient, then, consults the surgeon and either at his instance or at that of his usual medical attendant the anæsthetist is called in to undertake entire control of the patient so far as the anæsthetic is concerned. To him belongs the sole responsibility of his special work and his fee is appraised not by his surgical *confrère* but by himself. It is in the matter of the fee, we think, that Dr. GOLDAN makes out a strong case for his specialist colleagues. The fee of the anæsthetist should, Dr. GOLDAN maintains, be absolutely outside the control of the surgeon and its arrangement should be adjusted either between the anæsthetist and the patient directly or through the family medical attendant as an intermediary, and he narrates in his paper experiences which we should hope are unusual in America or elsewhere. In some instances, we are assured, he has been requested to accept a small fee and has subsequently found that this arrangement had been come to not only without the knowledge, but in direct opposition to the wishes, of the patient. On the other hand, we can well understand that some friction arose in certain instances which he cites where the fees of the anæsthetist largely exceeded the emolument claimed and received by the operator. We are informed that this reversal of the usual proportion of receipts occurred always when the danger to the patient lay rather in the anæsthetisation than in the use of the knife, but we cannot guess how a scale of emolument is to be fixed on such a principle, as fees are usually adjusted before an operation when no one can accurately forecast the directions from which danger may be anticipated. Nevertheless, a broader view of the responsibility and a more generous estimate of the money value of the anæsthetist's work should be accorded and we are glad to support Dr. GOLDAN'S contention even if he has advanced it in an extreme manner. While some few surgeons may fail to recognise all they owe to the skill of the anæsthetist and may regard the question of his fee as one over which they have a right to exercise absolute control, we have no doubt that there are many more who do full justice to their colleagues and who gladly acknowledge their indebtedness to the skill and acumen of the anæsthetist. The fees to be accorded for anæsthetisation are in this country largely questions of custom and individual usage. No doubt the correct thing is for the anæsthetist to be consulted as to his fee. If his own estimate exceeds that which the patient regards as a fair charge for his services his offer may be declined. Presumably the anæsthetist, like the physician or surgeon, knows what the correct and accepted fee is and can either demand it or decline to render his services for a smaller remuneration. It seems reasonable that the option should rest with him and not with others.

Whilst supporting the claims of the anæsthetist to estimate the pecuniary value of his services, we must regard the whole question of his position towards the patient from a broader point of view. Although cases may occasionally occur in which it would be advantageous alike to the patient, the surgeon, and the anæsthetist if the last-named were brought into closer relationship with the patient before, and even after, the operation, and in which a special fee should be determined by the peculiar circumstances of the case, yet we are convinced that Dr. Goldan has not quite grasped the necessarily more intimate relations which must exist between the surgeon and the patient. And possibly "Anæsthetist," in drawing attention to the belittling of the work of his fellows, does not quite take into due account the larger range of the surgeon's responsibilities. There must be a wide gulf between the relation of the surgeon and that of the anæsthetist to the patient. The surgeon's art is only limited by the extent of his knowledge of a field of work almost without boundaries and his responsibility is very great, for he has not only to determine what is best to be done in any given case—and the choice of practice is often very wide indeed—but he has to fight step by step through the dangers and difficulties of convalescence and to decide when to hold his hand and when to face the most heroic of procedures. Occasionally the surgeon's art may be confined to a trifling operation involving no risk, while the anæsthetist's part of the proceeding may involve risk to life, and in such cases it would be fair to accord a commensurate fee to him on whom rests the greater responsibility. These cases, however, are the exception and cannot be quoted to prove that in all instances the services of the anæsthetist must rank upon the same platform as those of the surgeon, as appears to be Dr. Goldan's contention. The surgeon who snubs the anæsthetist and is jealous of his advance in professional repute is, we hope, as extinct as the dodo; but the anæsthetist who claims more than common-sense and enlightened professional opinion are ready to accord to him is likely to do more harm than good to the status of himself and of his branch of practice. Dr. Goldan has taken this risk.

◆

The Death of Miss Hickman.

The mystery of Miss Hickman's disappearance from the Royal Free Hospital on August 15th was partly elucidated by the finding of her body in a plantation in Richmond Park on Oct. 19th and was fully solved at the coroner's inquisition which terminated on Nov. 12th when the jury returned a verdict of "Suicide whilst temporarily insane." Miss Hickman was a lady of high intellectual attainments, a qualified medical practitioner, and a person of conspicuous physical build, activity, and strength. We mention the last endowments because for a long time it was urged by her friends and accepted by a portion of the press that she had been kidnapped and either cruelly murdered or kept in durance, although common sense and all probabilities pointed to some other solution of her sudden and secret disappearance. From both direct and indirect evidence it is clear that the unfortunate lady felt an overwhelming sense of the responsibility she had assumed in engaging herself to act as locum-tenent for a house surgeon at the Royal Free Hospital. And here it may be remarked how unjust were the accusations brought against the governing body of that institution. They were suggested by expectation, both before and after the discovery of the body, that some other explanation than nervous breakdown would be forthcoming of Miss Hickman's departure from the scene of her professional duty.

What was the evidence against criminal homicide? In the first place Miss Hickman was not known to have had a personal enemy and her public position was such as to engender in the minds of others respect, and even reverence, rather than hatred or malice. The conditions under which her body was found almost negatived the theory that she had met with foul play. The body was discovered far from any habitation in a secluded copse fenced about with high railings, which to the height of some three or four feet were lined with wire netting. It was lying beneath some shrubs in an attitude of repose. There were no signs of a struggle having taken place. The remains had evidently not been disturbed save by marauding rodents and the agents of putrefaction which Brouardel has so aptly termed the "labourers of death." The exposed parts of the body, notably the head and neck, were destroyed to such an extent that the skull was separate from the body and several cervical vertebræ were completely disarticulated. It was this semblance of decapitation that probably incited the belief that a murder had been committed. There were no marks found on the vertebræ of an instrument having been used, a fact of forensic importance, since it is known how difficult it is even with a skilled hand to sever the head from the body and yet to leave no signs of the operation upon the bones. When the medical evidence had clearly proved that the ravages were only those of nature it was thought by some that the death might have been due to heart failure, as there was testimony that some years ago Miss Hickman had been pronounced the subject of cardiac weakness or disease. Her subsequent athletic life and manifestation of health rendered this hypothesis improbable. Besides, a person feeling faint would not be capable of the physical exertion necessary to transport her body from the open park to the stoutly fenced inclosure. The missing links in the chain of positive evidence were supplied by the following facts. Two or three days before she left the hospital Miss Hickman purchased 15 grains of sulphate of morphine; near the body there were discovered a hypodermic syringe and a measure-glass. The syringe contained traces of sulphate of morphine. We have it on the authority of Dr. Stevenson that from ten ounces only of portions of the viscera of the deceased he isolated one sixteenth of a grain of morphine, equal to one-twelfth of a grain of a morphine salt. This was a triumph of the analyst's skill, experience, and judgment, for it must be borne in mind that putrefaction was exceedingly advanced and that morphine is an alkaloid difficult of isolation from decomposed viscera.

Thus the solution, so far as human intelligence can solve it, of the sad problem which has exercised the public mind for so many weeks was reached when a coroner's jury returned a verdict that Miss Hickman came to her death from suicide by sulphate of morphine poisoning while temporarily insane. No other verdict could have been given by impartial minds after a review of the evidence tendered by the various witnesses and however great a shock may have been inflicted upon the relatives of Miss Hickman, still such a cause of death is less distressing to contemplate than violence. The motive for the act of self-destruction was the sense of mental strain brought about by over-estimation of responsibility in a person of hypersensitive nature. It would serve no purpose to try to trace the various steps which led to the abrupt breakdown of a normal and healthy mind. The fears which may and do affect the younger untried members of our profession are very real. Every medical practitioner has experienced such fears and the time of their occurrence seems very dark. Most men overcome them but some fall by the way. Each and all of us when confronted with a tragedy like the present may take to himself the words of LEAR and pray :—

> "Oh, let me not be mad, not mad, sweet heaven!"

◆

The Metropolitan Asylums Board and the Treatment of Consumption.

FOR some time past endeavours have been made at intervals to induce the Metropolitan Asylums Board to undertake the isolation of cases of pulmonary tuberculosis, and the most recent effort has taken the form of a resolution on the part of the Metropolitan Branch of the Society of Medical Officers of Health urging the Board to undertake the treatment of persons suffering from that disease. In the opinion of the society in question such treatment would be attended with great advantages to the public health, and it suggests that the Gore Farm Hospital at Dartford should be utilised as a sanatorium. This is a somewhat far-reaching proposal and the request, if acceded to, may lead to a very material development or modification of the work of the Metropolitan Asylums Board. The *personnel* and prestige of the Board are, however, such that before either rejecting or accepting the proposal the members will, we feel sure, ascertain carefully what are the advantages and what the disadvantages of such a step, and in their deliberations they will doubtless be called upon to review the effect of their past efforts in the direction of the limitation of certain of the acute exanthemata, the communicability of which is altogether different in degree from that of pulmonary tuberculosis.

With the view of aiding the deliberations of the committee appointed to consider this very important question we venture to draw attention to certain points which should, in our opinion, not be lost sight of. In the first place we notice that the word *treatment* is used and not the word *isolation* and the Board will do well to keep carefully this point before it in its deliberations. There can, we take it, be no question that all forms of disease—such, for instance, as whooping-cough, measles, and diarrhœa—would very materially benefit by treatment in the hospitals of the Board, and it will have to determine how far its statutory functions justify it in undertaking treatment as distinct from isolation. It is not clear from the report which has reached us whether the treatment referred to is to be confined to early cases, or whether it is contemplated that the Board shall also take under its wing patients in the more advanced stages of the malady : nor is it altogether obvious whether the public health advantages which are apparently urged as the basis of the proposal are claimed in respect of the withdrawal of infectious material, or with regard to the prolongation of life which those persons who are to undergo the treatment are likely to enjoy. The Board will doubtless go carefully into these points and the question of the cost of embarking upon this new enterprise is certainly not likely to be overlooked. But in estimating the cost the probable development of a departure such as this must be held in view. It will have to be borne in mind that it may be difficult, having once accepted the principle that the Board should deal with the tuberculous sick of the metropolis, to draw back; people practically of all classes below the opulent class, will not be slow to demand the continuance and expansion of the provision as a right. Moreover, it is not altogether improbable that the step might lead to interesting complications as regards the Poor-law cases and tuberculous patients who might otherwise find a place in the workhouse infirmary will be ready to discover means by which they may instead procure a bed at the proposed sanatoriums. Furthermore, cases of tuberculosis not at present resident in the metropolis may be attracted to London for a temporary sojourn in order to claim a heritage in its sanatoriums.

Then there will arise the questions as to the duration and object of the treatment. If it is proposed that the patients shall be kept under treatment until Koch's standard is attained—i.e., the absence of tubercle bacilli from the sputum—three months will be practically useless. If, on the other hand, "ability to work" is accepted as the standard it will be necessary to ascertain by how much such ability is likely to be prolonged by the length of treatment proposed. In order to arrive at a conclusion on this point the statistics of sanatoriums will have to be consulted, and seeing that in this country there is no compulsory insurance against breakdowns in health causing incapacity for work such as obtains in Germany, it is desirable that the statistics of German sanatoriums should be consulted, and in this connexion the methods adopted in compiling the statistics might profitably be inquired into. With regard to such headings in the columns of statistics as "able to work," "returned to work," "at work," and so on, it is necessary to keep before us the fact that, in the first place, many of these patients were at work when they entered the sanatorium and, in the second place, that having regard to the natural tendency towards recovery of the disease some of them might still have remained at work had they never entered the institution. So, too, with regard to the column "died in the sanatorium," a column which is not infrequently a blank, it would be well to ascertain how many patients were sent out from the institution shortly before their decease. In putting these few suggestions before the Board it must not be understood that we are in any sense hostile to the suggestion of the medical officers of health. On the contrary, we recognise that their action has been animated by humanitarian ideals and are only anxious that there shall be no over-statement and that the hopes of the people as regards the "stamping out" of the disease by sanatoriums alone shall not be raised to fever pitch merely to receive a bitter disappointment in the end. If the Metropolitan Asylums Board can raise half a million sterling to deal with tuberculosis let it be satisfied as to the best method of spending it before it commences the expenditure.

Bayliss v. Coleridge.

THE action for libel and slander brought by Mr. WILLIAM M. BAYLISS, assistant professor of physiology at University College, London, against the Hon. STEPHEN COLERIDGE, honorary secretary of the National Antivivisection Society, after occupying Lord ALVERSTONE and a special jury for several days, has ended in a verdict for the plaintiff for £2000 damages. The details of the evidence have been so fully reported in the newspapers that they need not be recapitulated. The cause of the action arose from the publication of a written statement by reading it at a meeting of the National Antivivisection Society held at St. James's Hall on May 1st, 1903, and also by causing it to be published in the *Daily News* of the following day. The statement was declared by the defendant to be that of an eye-witness and was as follows :—

"I have attended many lectures at the Physiological Laboratory of University College I have constantly heard while there the long drawn howling and whining like that of dogs in terror and agony. When the door of the lecture-room was opened the sound of this grew louder; when the door was again shut the cries seemed to be fainter. On Feb. 2nd this year I saw an experiment by Dr. W. M. BAYLISS on a dog at this laboratory. A big brown dog of the terrier type was brought into the lecture-room stretched on its back on the operation board. Its legs were fixed to the board, the head held firmly in a head holder, and it was muzzled so tightly that it was now deprived of every power to give audible expression to pain. In the skin of the abdomen there were several scarcely healed scars and wounds; on one of them that seemed rather fresh there were left a pair of clamping forceps It was evidently not the first time that the dog had had to serve science. The internal organs of the abdomen had surely had their turns of operations in previous experiments. The neck was opened widely for the stimulation by electricity of a certain gland. The dog struggled forcibly during the whole experiment and seemed to suffer extremely during the stimulation. No anæsthetic had been administered in my presence and the lecturer said nothing about any attempts to anæsthetise the animal having previously been made. When an anæsthetic has been given good care is generally taken to tell the audience about it and, as a rule, the anæsthesia must be kept up by repeated administration of the anæsthetic used. Nothing of the kind was done here and the violent and purposeful struggles of the animal indicated complete consciousness The dog was carried out still fixed to the board after half an hour." "Is not this," defendant asked, when he had read the above statement, "enough to make the blood run cold? If this is not torture, let Mr BAYLISS and his friends—Lord LISTER and Sir VICTOR HORSLEY—tell us in Heaven's name what torture is."

The meaning assigned by the plaintiff to these words was that he had been guilty of torture and inhumanity and had thereby rendered himself liable to criminal proceedings, and that he was unworthy to occupy his position or to hold the Home Secretary's licence. The defendant admitted the publication of the words but denied the meanings assigned to them, and said that in so far as what he had said consisted of matters of fact it was in its natural and ordinary sense true In so far as the words consisted of expressions of opinion they were published *bonâ fide* and without malice, and were fair comment on matters of public interest. In short, the jury had to say whether the allegations of fact were true. If upon this point their view was adverse to the defendant the question of "fair comment" would not arise

The verdict eventually arrived at will be regarded with approval and satisfaction not only by the medical profession but by the public, who in this case will be able to consider the allegations made, and the evidence called to support or to disprove them, with intelligent and dispassionate criticism. To the members of the National Antivivisection Society the verdict will probably bring no conviction; their views and their methods will remain unmodified, except perhaps by such caution as a hostile verdict accompanied by the payment of costs must necessarily tend to produce. To them Mr. COLERIDGE will presumably appear as a martyr and among them he will enjoy such additional regard as martyrdom may bring. To others his statement will figure as a typical example of the ways followed by "antivivisectionists" in their propaganda To anyone with the smallest knowledge of its subject-matter the story which Mr. COLERIDGE told carried its contradiction on the face of it. Even to the members of the society who cheered its narration it must have seemed to be one demanding careful scrutiny before it was made public. It imputed to a professor of physiology in a well known school of science not a secret infringement of the Act under which experiments upon animals are made, not a breach of that Act committed before a limited number of medical students in the medical school of a hospital, not an act committed by negligence or by inadvertence, but a flagrant and deliberate contravention of the law, a contravention involving wanton cruelty to a dumb animal, and one laying the operator open to a severe penalty. The alleged illegal act was, moreover, committed before a large mixed class of students at University College, which class two ardent lady "antivivisectionists" found no difficulty in attending and to which as many more of like sympathies could have gone had they been minded to comply with the usual formal conditions. The "antivivisectionists" who accepted such a story, even when related of a physiologist, without to some extent suspecting its accuracy, well exemplified the saying, "*quem Deus vult perdere prius dementat.*" That the success of the demonstration made by means of the animal in question would not have been enhanced by its consciousness, but would, on the contrary, have been destroyed thereby, they naturally would not consider; indeed, in the course of the trial it was suggested, on the defendant's behalf, that the supposed better performance of the experiment was the reason for the absence of anæsthesia alleged by his principal witnesses. Upon this question as to whether there was anæsthesia or not the issue of the trial depended, and it must be borne in mind that the allegation of Mr. COLERIDGE'S witnesses, two Swedish lady students (who, by the way, were members of antivivisectionist societies in Scandinavia) was not that there was an accidental or temporary return to consciousness on the part of the dog but that the animal was conscious when it was brought into the theatre for the purpose of the plaintiff's demonstration, and throughout that demonstration Their tale was not that they did not see the apparatus by which the A.C E. mixture was being supplied in order to maintain the condition of anæsthesia and by which artificial respiration was being maintained, but that they examined the dog closely, that there was no tube in its trachea when it was being brought into the theatre, and that tracheotomy had not been performed upon it. In accepting the evidence of these witnesses before he told their story at a public meeting in St. James's Hall the defendant must have considered them to be perfectly honest in their intent. The Lord Chief Justice, in summing up to the jury, directed them that these young persons, upon whose testimony the whole of the defendant's case depended, no doubt believed in all that they had stated. But whatever the views of the defendant as to the personal character and the convictions of his witnesses may have been, it might have occurred to anyone not blinded by preconceived opinion to ponder the question whether their knowledge and experience were sufficient to render them worthy of implicit reliance, whether, despite their good faith, they were, in fact, trustworthy witnesses upon the questions as to which their evidence was of vital importance to him. It might also have occurred to him, as no doubt was realised by his legal advisers and by the jury, that among the students who attended this particular lecture of Mr. BAYLISS there might be some no less observant, no less humane, and no less honest than the two foreign ladies upon whose assertion he decided to risk his own reputation as the narrator of truth. The Lord Chief Justice put to one of these ladies, at the conclusion of her evidence, a most pertinent question when he asked her whether any person of ordinary intelligence and observation, having her opportunities to observe, could not have seen all that she had deposed to. Her answer was in the affirmative, yet there was no evidence forthcoming that any other witness of "violent and purposeful struggles" on the part of the dog "indicating complete consciousness" was ever sought for among either the men or the women present.

In contradiction of the story told by the defendant's witnesses there was the perfectly clear and distinct evidence of fact given by the plaintiff and the two gentlemen whose conduct like his own was impugned by the libel, and their evidence upon this and every other point material to the plaintiff's case was corroborated by the unimpeachable testimony of independent witnesses. In the circumstances it is not surprising that the result was such as has been recorded. The only source of surprise should be that the "antivivisectionist" section of the community, of whose methods this libel was a typical instance, should have so completely abandoned all ordinary caution in conducting their campaign. For Mr. BAYLISS and Dr. STARLING, against whom this particular attack was directed, we have nothing but congratulation upon the result of the action. A jury is perhaps not the best possible tribunal before which to investigate questions arising out of the necessities of scientific research but in this instance the issue was too plain to be mistaken or obscured.

Annotations.

"Ne quid nimis."

EPSOM COLLEGE.

As we go to press the governors of the Royal Medical Benevolent College, who were called together by the council of the College last week, are meeting to receive a recommendation from the council that the title of the institution in future shall be "Epsom College" in all documents relating to the school. In all papers connected with the charity it is proposed that the title shall run "Epsom College, established in 1855 as a Public School, with a Royal Medical Foundation." This step has been rendered necessary in the opinion of the council in consequence of the widespread and continuous misconception that the present title indicates that the College is a class school and a charity school. There is plenty of evidence that it was in no wise the intention of the founder to establish an institution with any such limitation or scope. We are informed that the same scale of help will be continued to the pensioners and foundation scholars as heretofore, but strenuous efforts will be made to obtain and to capitalise the sum necessary to make the medical foundation secure. We wish the ruling body of Epsom College every success in its efforts. The record of the school amply justifies the statement, made and re-made in these columns, that we have in Epsom College a first-class public school. The proposed change of title will help the public to appreciate this fact with regard to the school, while the financial policy that has been pursued with conspicuous success for many years ought, we think, now to culminate in the placing of the charitable side of the institution upon a sound basis for all time.

THE LEGAL OBLIGATION TO PROVIDE MEDICAL AID FOR CHILDREN.

IN England the followers of Mrs. Eddy have long exercised a wise discretion in the matter of procuring for the children under their control that medical aid with which they must themselves dispense if they would faithfully obey the precepts of their prophetess. They have, in short, been aware that to neglect to procure medical aid for a child might involve them in a serious criminal charge and they have accordingly obtained it. In Canada they will now presumably follow the same course, for the Court of Appeal of Ontario has held in the case of a "Christian scientist", that medical aid is a "necessary" within the meaning of a section of the Criminal Code of the Colony which makes a parent liable for omitting to provide necessaries for a child under 16 years and that where death follows the omission the parent may be convicted of manslaughter. In England, under the Poor law Amendment Act, 1868, it used to be an offence for any person "wilfully to neglect to provide adequate food, clothes, medical aid, or lodging" for his child whereby the child should be, or should be likely to be, seriously injured. This section which apparently contained an attempt to define the "necessaries" referred to in the Canadian Code is now repealed and under the Prevention of Cruelty to Children Act, 1894, any person having the custody or care of any child is guilty of a misdemeanour if he or she "wilfully neglects such child in a manner likely to cause such child unnecessary suffering or injury to its health." The omission of any direct reference to medical aid in the newer Act rendered it necessary to have recourse to the Court for Crown Cases Reserved in a faith-healing case where death had resulted. In that case[1] Lord Russell of Killowen, L.C.J., pointed out that "it would be an odd result if we were obliged to come to the conclusion that in dealing with such a subject as the protection of children the law had meant to take what may be described as a retrograde step"; and the Court unanimously upheld the conviction for manslaughter. In the case before the Court of Appeal of Ontario the indictment was under a section of the Criminal Code of Canada[2] which is as follows: "Everyone who as a parent, guardian, or head of a family is under a legal duty to provide necessaries for any child under the age of 16 years is criminally responsible for omitting, without lawful excuse, to do so while such a child remains a member of his or her household, whether such child is helpless or not, if the death of such child is caused, or if his life is endangered or his health is or is likely to be permanently injured by such omission." The questions raised upon this were whether the term "necessaries" included medical treatment and whether the Chief Justice of the King's Bench Division of Ontario, the Hon. Glenholme Falconbridge, who tried the case, had rightly directed the jury that the evidence of witnesses that they had been cured or benefited by "Christian science" treatment had no bearing on the case except as showing the good faith of the prisoner. In deciding the first in the affirmative the Hon. Charles Moss, Chief Justice of the Court of Appeal, Ontario, laid down that "what is included in necessaries is to be determined upon the circumstances of each case, and whether there has been neglect to supply them must also depend upon the circumstances" This would protect the parent who believing his child's case to be of a trifling nature did not consider medical aid to be necessary, although, in fact, it was necessary, and would leave for the jury the question whether in all the circumstances of the case "medical assistance and treatment were necessaries proper to be provided for the child having regard to the state and condition in which the evidence showed him to be." With regard to the evidence of "Christian science cures" the learned Chief Justice held that they were properly excluded from the jury's consideration upon the main issue as to whether necessaries had been provided or not, and that as the good faith of the prisoner was not in question the evidence should not have been received at all This eminently sensible and satisfactory decision should result in the saving of an appreciable number of children from death or injury to their health at the hands of "Christian scientists" and other absurd but dangerous people, although the section of the Code which it interprets does not go so far as the British Act which makes penal the causing of "unnecessary suffering." Both the decision in R v. Lewis, the case before the Court of Ontario, and that in R v. Senior, referred to above, are, however, no more than we were entitled to expect. A serious slur would be cast upon medical science in the present day if our law courts refused to recognise its aid as necessary in cases of serious illness or injury where relief is desired or denied its power to alleviate suffering.

"ALL PHILANTHROPISTS."

A CORRESPONDENT sends us a report of some remarks made at Bow county court by his honour Judge Smyly in a recent case. The words speak for themselves and require no comment of ours to emphasise the mischievous and belittling attitude of mind of one in a position of public authority towards a hard-working and non-assertive profession. The West Ham guardians sued a man named Gringer for a certain sum which included half a guinea for the medical examination. We now quote the newspaper report. Defendant said half a crown was enough for the doctor. His Honour: But this is for an examination. Mr. Gringer: Well it seems a bit thick to me. His Honour: I think the medical fee is too heavy. The heavy fee was accordingly reduced on his honour's decision to five shillings. Our correspondent remarks: "What would the judge have said in his barrister days if he had been offered 5*s*. for an opinion even which involved no legal responsibility?" We can only echo "What?" The informant further embarks upon the thorny question of fees to medical men as witnesses. His opinions are such as we have often pronounced and supported. When he asks for help from us by advice as to what steps to take in the matter we are forced to confess helplessness. Unless combined effort on the part of the medical profession can induce an influential parliamentary representative to take up the matter we see no hope of any alteration in the law. Until then medical men must rest content to be paid one guinea while they attend county courts and lose the time and remuneration from their practice that such attendance occasions. Our correspondent writes, "At Whitechapel county court I was subpœnaed lately and after waiting till 4 P.M. my case came on. As no fee was guaranteed I said, 'Before being sworn, your honour, I beg to state that I have had no fee and see no prospect of getting one.' The only answer that I got was, 'I am very sorry for you, because if you do not give evidence I shall fine you. You are all philanthropists and must do it gratuitously.' If this is law it is not equity, and I do not see why law should be different in the high courts from what it is in the county courts. It is absurd to expect a man to waste a whole day with the vermin of Hebrew aliens crawling over him for such a sum as one guinea. I never go to an accident without the fear and dread of a wasted day at the county court hanging over me." We sympathise cordially with this gentleman. And we have known practitioners of experience to flee from the scene of a street accident. The damage to the public thus caused by the present arrangements is obvious

THE PATHOLOGY OF CEREBRAL RHEUMATISM.

LITTLE has been written on the pathology of cerebral rheumatism, for only recently has a technique been elaborated sufficient to reveal the fine changes which occur in the nerve cells. At the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 16th M. Josué and M. Salomon described the following case. A woman, aged 38 years, was admitted to hospital on July 25th, 1903. Her illness began four days previously with sore-throat. Soon the feet became painful and then the knees, the hips, the wrists, the elbows, and the shoulders. Violent headache and abundant perspiration followed. On admission she was delirious. The face was red and grimacing and from time to time presented spasmodic contractions. The pupils were contracted. There were convulsive jerkings and disordered movements of the limbs. The joints of the feet and the left elbow and the wrist were swollen and the overlying skin was red and hot. The right knee-joint was full of fluid and hot. On the 26th the temperature was 102·5° F. in the morning and 104·5° in the evening. The heart sounds were muffled but there was no murmur. There was marked dyspnœa out of proportion to the physical signs which consisted of some subcrepitant râles at the bases of the lungs. The urine contained a trace of albumin. Sodium salicylate was given On the 27th the evening temperature was 103 5° and the delirium persisted. On the 29th the delirium was less violent, the face was cyanosed, and there were bronchitic râles all over the chest. The evening temperature was 104°. On the 30th the delirium was violent and the patient tried to get out of bed. Death occurred in the night. At the necropsy the brain was found to be very congested, especially in the frontal lobes and at the base. The cerebro-spinal fluid was not more abundant than normal. The right knee-joint contained thick cloudy fluid. The lungs were congested and œdematous at the bases. There were some filamentous pleural adhesions. There was no endocarditis but on the aorta at the origin of the coronary arteries were some gelatinous patches. Sections of the frontal lobe and of the motor region of the brain were stained by Nissl's method. In the frontal lobe the meninges showed no signs of infiltration with leucocytes but the nerve cells were profoundly altered. Everywhere the chromatophile granules had disappeared. The achromatic substance had a uniform tint and a granular appearance and seemed to have a tendency "to fragment." Some cells were fissured. The nucleus was more stained than normal. In many sections "neuronophagia" was observed. In some places cells were attacked by two or three "neuronophages" which dug out a sort of notch; in others, all the protoplasm of the cell had disappeared, leaving only the nucleus with one or several neuronophages in a vacuole; finally the cell was completely destroyed, leaving only a mass of neuronophages in a clear space. The neuronophages were of two kinds: some had a large clear nucleus and resembled macrophages; others had a small nucleus and the appearance of lymphocytes. In the motor area the meninges showed a mononuclear leucocytic reaction. The changes in the nerve cells were a little different from those of the frontal lobe. There were fewer neuronophages and the nerve cells were less affected. In the vessels of the pia mater were large diplococci and bacilli taking Gram's stain and in the pia mater itself and in certain cerebral capillaries were diplococci. Thus there was in the brain a striking contrast between the trivial macroscopic and the intense microscopic lesions.

EPIDEMICS AND EARTHQUAKES.

Do earthquakes set microbes in motion or do they only affect the nerves? From early times pestilence has been regarded as one of the accompaniments of earthquakes. Nor is this perhaps a mere figment of superstition. Many instances of epidemics following upon earthquakes are on record. Thus, in 557–60 A.D., earthquake years, Constantinople was visited by a pestilence and in 615 A.D., after more than a decade of seismic disturbances which extended from Japan to the Mediterranean, the whole of Italy was visited, according to Sigonius, by a fearful epidemic, of which the nature is not recorded. Old writers, such as von Plenciz, an authority on the Lisbon earthquake of 1755, were wont to attribute the proneness to disease exhibited by whole populations during earthquake seasons to shaken nerves begotten of prolonged suspense and broken rest at night. Von Plenciz particularly notes in this connexion the comment of Seneca upon the great apparent increase in the number of lunatics and imbeciles after the destruction of Pompeii and Herculaneum. An earthquake in the Alps, probably accompanied by vast landslips, must have been peculiarly terrifying even to mountaineers of strong nerves. Such a disturbance occurred throughout Switzerland in April, 802 A.D., and it was followed by a "fearful pestilence" according to the "Diarium Historicum" of Bertrand. Again the nature of the disease is left undescribed, but in 842 A.D. we are told specifically by Dom Bouquet that a severe "tussis," from which many died, followed an earthquake which shook almost all northern Gaul. England became an earthquake centre in the eleventh century, when a sensible mortality among man and beast succeeded violent shocks in Worcester, Derby, and the West. It is remarkable, however, that though England was afterwards subjected to many shocks, which were usually preceded or followed by periods of violent rain or cold, the country does not seem to have been visited again by diseases accompanying earthquakes. The mainland of the Continent continued to suffer from these epidemics, especially Switzerland, Italy, and Carinthia, while England remained immune—that is, if the old chroniclers, such as Baker, are to be accepted as unimpeachable witnesses in the matter.

HERPES OF THE FIFTH NERVE WITH OCULAR PARALYSIS.

In the *British Journal of Dermatology* for September Dr. Arthur J. Hall has recorded the following case which presents several points of interest. A man, aged 66 years, was admitted to hospital on March 23rd with paralysis of the left third and fourth nerves. Eight weeks before he was attacked with severe pains on the left side of the forehead where, as well as on the same side of the nose, blebs soon appeared. He could not open the left eye and when he pushed up the lid he saw double. The blebs healed, leaving scars. On March 14th he went to hospital. There were paralysis of the left third and fourth nerves and congestion of the conjunctiva. On March 21st he was seen again and complained that two days previously he had severe pain in the right eye. There were partial paralysis of the right third nerve and iritis. On admission the paralysis of the right third nerve had disappeared but that of the left third and fourth nerves remained. In the area of distribution of the nasal and supra-orbital branches of the fifth nerve there were scars. The urine contained 4·5 per cent. of sugar but there was no polyuria, thirst, or wasting. The knee jerks were diminished. The paralysis gradually diminished. On May 5th it had practically disappeared but an inflamed papule remained on the lower part of the conjunctiva. In the meantime under a restricted diet the glycosuria was reduced to 3·5 per cent. Paralysis of the third and fourth nerves, associated with herpes ophthalmicus of the same side, is well recognised, but the intercurrent paralysis of the third nerve on the other side which occurred in this case must be exceedingly rare. Bilateral herpes is not unknown but, as Dr. Hall points out, herpes ophthalmicus with associated paralysis on one side, followed by paralysis without herpes on the opposite side in the same area, does not appear to have been previously observed. The explanation seems to be, as he suggests, that the patient was suffering from diabetes, in which ocular paralysis is not uncommon. The diabetes was probably the cause of the right-sided intercurrent paralysis and possibly of the left-sided paralysis and herpes. Though neuritis is not uncommon in diabetes herpes seems to be so.

THE ACCIDENT TO LORD KITCHENER.

Everyone will have heard with sincere regret of the accident to Lord Kitchener in having sustained a fracture of both bones of the leg. From the somewhat scanty reports which have come to hand it appears, however, that the fracture is a simple one and such an accident, though tiresome, is not, as a rule, dangerous. Neither is its repair such a weary business as was the case 20 or 30 years ago when a broken leg meant confinement to bed with the leg in splints for at least five weeks, then another three weeks in plaster, and finally a long period of weakness while the muscles disused for so long were recovering their function. Nowadays, however, owing to the modern method of treatment by splints combined with massage from a very early period the time of convalescence is much shortened, the patient being able to be on the sofa in about a fortnight, and consolidation taking place in about a month, while the muscles by the time that the patient is allowed to walk are almost as active as before the accident. The latest reports state that Lord Kitchener is progressing favourably and there is every reason to hope that this condition will be maintained.

BREAKING UP THE STREETS.

After a too short interval Bedford-street, Strand, is "up" once again. This time the disturber is the New River Company. Last time, if we remember right, it was the electric light. We humbly appeal to the gas company, to the telephone companies, both the National and the Post Office, to the hydraulic power company, to the telegraph authorities, to the drainage authorities, and to anyone else who may want to dig to come quickly while the broken road is in the way with them, and not to wait until the holes have been filled and the new wood paving has been put down. Not that we suppose these august bodies will listen to our appeal and we foresee a weary vista of road-breaking which will last till well over Christmas. Then by the time that the wood pavement has been relaid for the sixth time it will be the turn of the electric light again, and so on *ad infinitum*. It would not be a bad thing to close completely a short street here and there for a space of six months and to turn loose the various road-breaking authorities to play there in the same way as the London County Council provides sand pits for children to dig in. This plan would give employment to deserving or undeserving workmen and would concentrate an unbearable nuisance into a small area. In September the Brompton road was closed and repaved with wood. The road is now "up," for a newly paved roadway attracts road-breakers as sugar does moths. They cannot keep away from it. But when will London be free from the expense and the nuisance of perpetual road-breaking?

RETIREMENT OF MR. F. C. ABBOTT.

WE much regret to learn that, acting on medical advice, Mr. F. C. Abbott has felt compelled to give up his work as assistant surgeon at St. Thomas's Hospital and at the Evelina Hospital. The severance of Mr. Abbott's connexion with St. Thomas's Hospital and the sudden interruption of a brilliant career there and elsewhere are felt by his colleagues and friends to be a genuine misfortune for surgery. We are glad to know that the reason which has led Mr. Abbott to consider it his duty to give up work as an operating surgeon will not prevent his active pursuit of surgery as a profession. He is the victim of a very rare condition of the retinal arteries from which his father suffered before him. This condition, while not interfering with visual activity in a bright light, causes great difficulty in distinguishing objects when the illumination is indifferent—the symptom commonly known as "night-blindness." The inconvenience resulting from this defect had of late become more obtrusive and consequently Mr. Abbott has considered it wise to abandon the career of an operating surgeon on which he had embarked with such signal success and to take up while still young some other branch of professional work in which acute visual perception in a poor light may be less essential. We tender our sympathies to Mr. Abbott in a situation that must be very painful to him, while we add our assured hope that he will succeed in the somewhat different field of enterprise on which he proposes to embark.

THE REDUCTION OF DISLOCATION OF THE CERVICAL SPINE.

IN the *Boston Medical and Surgical Journal* of Oct. 22nd Dr. G. L. Walton has published an important paper on cervical dislocation and its reduction. He points out that cervical dislocation is not, as may be supposed, a pathological curiosity but an accident which any practitioner may encounter and which is capable of speedy relief by appropriate treatment. The methods in vogue—traction with or without abduction and rotation, and abduction and rotation without traction—are not very satisfactory. Careful study of the displacement has led Dr. Walton to the conclusion that dorso-lateral flexion combined if necessary with slight rotation is the best treatment. In the lumbar and dorsal regions the articular processes are so upright that dislocation can hardly occur without fracture, but in the cervical region they are more horizontal and the articular process of one vertebra may slip forward on the next and fall into the intervertebral notch. More rarely both articular processes of a vertebra are dislocated. Supposing an articular process on the left side has slipped forward the head will be rotated so that the face is turned to the right. If the articular process has slipped down into the intervertebral notch the head will in addition be tilted to the left, but if the process has been caught on the crest of the one below the head will be tilted to the right. Thus the side on which the dislocation has occurred can be determined by the direction in which the head is rotated. In bilateral dislocation the head is carried forwards and tilted directly backwards. The only conditions with which dislocation is likely to be confounded are torticollis and vertebral disease (caries). In torticollis, if the head be rotated to the right and tilted to the left, the left sterno-mastoid will be contracted. In a similar position produced by unilateral dislocation the left sterno mastoid will be lax and the right more or less on the stretch. In caries the history will assist the diagnosis. In most cases of unilateral dislocation there is no paralysis; the nerve roots escape pressure. But in two cases Dr. Walton observed paralysis and in a case of bilateral dislocation there was spastic paralysis from pressure on the cord. The method of reducing a unilateral dislocation is as follows. Suppose a left articular process has slipped forward into the intervertebral notch. If the patient be facing north the head must be tilted south east. Slight rotation in the direction towards which the face is rotated (the right) may be necessary to free the process. Rotation in the opposite direction will then complete the reduction. During the operation the patient should be sitting and the head should be rocked without traction, for traction lessens the effectiveness of the fulcrum necessary for reduction. The period after dislocation in which reduction is possible has not been determined but it exceeds six months.

THE REMOVAL OF KING'S COLLEGE HOSPITAL.

ON Nov. 12th an appeal was issued from King's College Hospital for funds in connexion with the projected removal of the institution from its present site. The appeal states that London as a whole, excluding the City of Westminster, is woefully deficient in provision for its sick poor, while South London, whither it is proposed to remove the hospital from its present site in Portugal-street, is particularly so. The sum of £300,000 is needed to carry out the scheme of removal and to build and to equip the hospital upon the new site, although the site has already been most generously given The chief reasons which led to the decision to remove the hospital are stated to be that the existing building is obsolete in design, inadequate in accommodation, and incapable of adequate extension or remodelling, while the poorer inhabitants of the neighbourhood have gone to other and distant parts of London. Although King's College Hospital will be removed to South London it is expected that patients will continue to be sent there from all parts and it is claimed that the hospital will still be a national institution and therefore should be nationally supported. Of course it must be remembered that in every case where a bigger building and more accommodation are obtained a correspondingly larger income at least will be necessary to maintain the hospitals not only up to the level of their previous efficiency but also to keep pace with the rapid progress of modern methods of treatment which in many cases entail a larger expense. This no doubt explains the constantly increasing expenditure of hospitals in the maintenance of patients to which the special attention of the committee of distribution of the Metropolitan Hospital Sunday Fund has been directed.[1] Of course, there is no doubt that in many cases the governors are quite right in believing that when they can show a building worth having, admiring, and cherishing it will stimulate observers adequately to support it. If the duration of a patient's sickness can, by slightly increased expenditure, be shortened without the loss of efficiency there will be in many cases a considerable saving in the wealth-producing power of the worker which will benefit the country at large. Those who intend practically to support the removal scheme may find particulars of where to send their donations in the letter from the governors in our issue of Nov. 7th, p. 1324.

---

[1] THE LANCET, August 8th, 1903, p 410.

THE PROFESSOR OF SURGERY AT THE UNIVERSITY OF CAMBRIDGE.

THE public orator, Dr. Sandys, spoke as follows in recently presenting for the complete degree of Master of Arts *honoris causâ* Mr. Howard Marsh, the newly elected Professor of Surgery:—

> Haud ita pridem, ut meministis omnes, plenus annis, plenus honoribus, e vita excessit vir insignis, per annos plurimos primum anatomiam, deinde chirurgiam, inter nosmet ipsos praeclare professus. Qui qualis quantusque vir fuerit, quanto scientiæ amore, quanta animi alacritate, quanta sermonis facundia praeditus, non est quod longius exsequar: vosmet ipsi vobiscum recordamini. Chirurgiae vero professoris nostri primi in locum, annorum septem intervallo interposito, nuper electus est vir egregius, quem, tot aliis ministrum salutis, Academiae nomine hodie ipsum jubemus salvere. Viri talis autem inter laudes, non nostrum erit hodie scientiae tam reconditae penetralia perscrutari, non artis intimae mysteria occulta et abstrusa in lucem proferre; ne corporis quidem mala illa dura verbis duris expressa, ut ἀρθρῖτις, ut ἀγκύλωσις, totiens ab hoc viro feliciter levata, coram vobis hodie commemorabuntur. Mentis potius ad bona praeclara transibimus, et professorem nobis nuper datum propterea praesertim animo laeto accipiemus, quod ingenio tam vivido, judicio tam subacto est præditus, in rebus minutissimis observandis tam subtilis, in rebus obscurissimis explicandis tam lucidus. Viro in ea parte medicinae quae manu curat insigni manus libenter tendimus, dextraeque tam sollerti dextram libenter jungimus. Duco ad vos baronetti quidem illustris, Jacobi Paget, quondam adjutorem, equitis autem insignis, Georgii Humphry, nunc demum successorem, virum nobis omnibus acceptissimum, Professorem Marsh.

The public orator at Cambridge has a knack of saying nice things in the nicest way as well as in unimpeachable Latin. We are sure that Professor Marsh's friends and pupils will appreciate the kind sentiments expressed towards the new Master of Arts of the University of Cambridge, while all our readers will endorse the praise given in memory of Paget and Humphry.

MUSIC AND MADNESS.

BY the above heading we do not mean to suggest that Hector Berlioz, whose centenary occurs this year, was mad, but the vague aspirations, the longings, the loneliness, and the horrible visions of insanity were surely never more powerfully set forth than in that master's *Symphonie Fantastique*, a most powerful rendering of which was given at Queen's Hall, London, on Nov. 12th, by Herr Felix Weingartner and the magnificent band under his control. The protagonist of the symphony is a musician who is possessed by an "*idée fixe*" naturally connected with a woman with whom he is in love. The first movement gives this *idée* and illustrates his longings and in the second movement he sees his love at a ball. Here the lights and the swirl of the dancers are marvellously illustrated by the glitter of harps and the shimmer of a waltz theme played by the muted strings. In the third movement the scene is laid in a pastoral country where a melancholy shepherd illustrated by a theme for the *cor anglais* calls to his love who answers him on the oboe. The duet continues for some time and finally the *cor anglais* calls for the last time but elicits no response but the mutterings of a thunderstorm. The young musician concludes from this that his love is hopeless and so takes opium to end his misery. He only takes enough, however, to give him fearful dreams, the subject of which is his own march to execution for having killed his love. The dismal procession is set forth with wonderful skill. By means of the throbs and mutterings of the drums and of the double-basses we find suggested the tramping of feet and the many-voiced cries of the attendant crowds which haunt the hearer with a horrible sense of uncanny surroundings. With a crash the axe falls but the hero's sufferings are not over, for although he is dead he is now at a witches' Sabbath, where the theme of his "*idée fixe*," hideously burlesqued and vulgarised, is piped on a clarionet while the assembled witches jeer. Under all pulses the terrific plain chant of the *Dies Iræ*. It is not soothing music but so far as one man can enter into another's brain and convey his sensation to others Berlioz has certainly made his music a means to so doing. Medical men who have not heard this work should take the first opportunity of repairing their neglect.

CHOLERA IN EGYPT.

FROM a return recently issued by the Egyptian Sanitary Department we learn that 20,976 cases of cholera were treated in Government hospitals during 1902. Of these 14,958 cases died and 6018 recovered. There were also 19,637 deaths "out of hospital"; the total mortality consequently amounted to 34,595. The number of infected villages was 2026. No comments of any kind accompany the return which is purely statistical, but some idea of the work done by the Egyptian sanitary officials can be obtained from the figures. Every one of the infected villages had to be taken in hand with a view to disinfection, to say nothing of the large towns and "governorates," in which 3393 deaths occurred out of an aggregate population of 1,000,000. It is more than probable that rural Egypt has never been so clean before. It speaks volumes for the tact displayed by Sir Horace Pinching and his subordinates that all the necessary demolition, whitewashing, and sweeping were accomplished without the slightest friction and it is also greatly to their credit that they were able to deal with, and to control, an important epidemic without causing a panic. Not only has the confidence of the *fellahin* been secured but also that of the more impressionable Greek and Syrian inhabitants.

A SPECIALIST IN CRIME.

ON Nov. 10th at the County of London Sessions a man named William Smith pleaded guilty and was sentenced to three and a half years' penal servitude for a series of ingenious robberies perpetrated upon medical practitioners in the metropolis. There were more than a dozen cases against him and he had before served two sentences of imprisonment for like acts. His method was to watch for a medical man to pass on his professional rounds or else to entice him out to pay a visit to an imaginary patient by means of a bogus message. He then called at the house and on being informed that the medical man was out asked to write a note. In the course of writing it and of leaving the house he usually contrived to annex some portable article, such as an ornament from the room or an umbrella from the hall. Medical men who have read the story of his depredations will do well to instil caution and vigilance into their servants, for although the sentence recorded may serve as a warning to other criminals the success which for some time evidently attended the efforts of this rascal has been made equally conspicuous by the reports of the case in the newspapers. Medical practitioners have to take with the rest of the community their share of the inconvenience and loss which dishonest persons can always cause to their victims; it is a little hard upon them that circumstances should expose them in a greater degree than others to the devices of criminals who choose to devote their attentions as "specialists" to the medical profession.

THE ASSOCIATION OF RICKETS AND WEAK-MINDEDNESS.

THAT some association exists between certain forms of rickets and weak-mindedness in children seems to be a conclusion in favour of which evidence of a satisfactory character has been accumulating in recent years. In a previous annotation in THE LANCET reference was made to the observations of Dr. Renoult of Paris with regard to the connexion of rickets with weak mindedness[1] In a communication read at the recent Congress of French Alienists and Neurologists held at Brussels and published in the *Archives de Neurologie* for September Dr Bourneville and Dr Lemaire of the Bicêtre Hospital, Paris, having been struck with the frequency of the association of rickets and weakmindedness, state that they were led to investigate systematically a number of cases of the nature referred to in order to find a satisfactory answer to the question, "Does there exist a relationship between the disorder of nutrition which underlies rickets and arrest of mental development in the child?" It was found that rachitic changes of unmistakeable character were present in 34 out of 435 patients in residence The latter comprised idiots, imbeciles, and feeble minded children, the proportion of rachitic cases amongst these amounting to 8 per cent The malformations noticed were in descending order of frequency beaded thorax deformity of the skull, facial asymmetry, and dental anomalies Five cases of scoliosis and six of excessive curvature of the tibia were also noticed Pelvic deformities were met with in only two cases Another fact was also clearly shown—viz, that the mental backwardness of the patients was generally not congenital Such infants appeared to be of normal intelligence during the first few months of their life and it was only at the age of one and a half or two years that symptoms of idiocy manifested themselves The majority of the children were free from anatomical "stigmata of degeneracy" apart from the special deformity of rickets, a fact which suggested that the defect of the nervous system could not have been produced in the period of fœtal life It was frequently noticed that the mental weakness of the rachitic patients referred to above made its appearance after an attack of infectious broncho pneumonia or gastro enteritis It was also noticed that while in many cases mental enfeeblement was the sole sequel of the pulmonary or gastro intestinal infection in a few cases rachitic deformity of the bones alone resulted and that the relationship of these sequelæ to one another was such as to suggest that one and the same toxic or infectious agency was the cause of brain degeneration (weak mindedness and imbecility) and of disease of the osteogenetic process (rickets) A number of photographs were shown by Dr Bourneville and Dr Lemaire in support of these statements

A PROVINCIAL sessional meeting of the Sanitary Institute will be held at the town hall, Leicester, on Saturday, Dec 5th, at 11 A M, when a discussion will take place on the Collection, Disposal, and Utilisation of Town Refuse in Leicester, to be opened by Mr Frank W Allen of Leicester A visit will afterwards be paid to the destructor works On Dec 9th at 8 P M a discussion will take place at the Parkes Museum, Margaret-street, London W, on the Flooding of Basements in London by Sewage, which will be opened by Mr Maurice Fitzmaurice, C M G, and Dr H R Kenwood, and general discussion is invited The chair will be taken by Sir Benjamin Baker, K C M G Tickets for admission of visitors may be obtained on application to the secretary, Mr E White Wallis, at the Parkes Museum

Dr Allan Macfadyen will deliver a lecture at the Lister Institute of Preventive Medicine, Chelsea gardens, London, S W, on Thursday, Dec 3rd, at 9 P M, on Intracellular Bacterial Toxins and their Practical Application

THE medical officer of health of the Cape Colony states that for the week ending Oct 24th only two cases of plague were discovered in the Colony—namely, two coloured males, one being found dead, both discovered on Oct 19th As regards the Mauritius a telegram from the Governor received at the Colonial Office on Nov 13th states that for the week ending Nov 12th there were 81 cases of plague and 48 deaths from the disease

THE Dutch Government having appointed a well known Zurich homœopath—who, by the way, was originally a pastor—to the chair of Pharmacognosis and Pharmacodynamics in the University of Leyden, in opposition to the wishes of the medical faculty, a considerable amount of interest has been excited in Dutch scientific circles as to the results of the quarrel

THE annual dinner of past and present students of the National Dental Hospital and College, will be held at the Trocadéro Restaurant, Piccadilly circus, London, on Friday, Nov 27th The chair will be taken by Mr Tweedy, President of the Royal College of Surgeons of England

THE autumn dinner of the Irish Medical Schools' and Graduates' Association will take place at the Trocadéro Restaurant, Piccadilly circus, on Wednesday, Nov 25th, at 7 30 P M The President, Dr P S Abraham, will take the chair

Mr T H Openshaw, F R C S, C M G, surgeon to the London Hospital, has been appointed by the Metropolitan Asylums Board honorary consulting surgeon to the training ship *Exmouth* at Grays

OUR Berlin correspondent, writing on Nov 16th, confirms the satisfactory reports which have appeared in the daily press as to the German Emperor's recovery from his recent operation

Sir Hermann Weber will deliver a lecture on Thursday, Dec 3rd, at 5 P M at the Royal College of Physicians of London, on the Means for the Prolongation of Life

THE death is announced, in the eightieth year of his age, of Sir Robert Martin Craven, the well known surgeon of Hull

THIRTY-SECOND ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD (1902 03)

THE more purely medical matters which come under the very wide head of local government having been dealt with at great length in the annual report of the medical officer of that Board, which we have already reviewed,[1] it is by no means easy to make choice of matters to consider in the report now under consideration for that report consists of nearly 1000 pages of matter, including tables of statistics and charts Local government concerns itself with nearly everything which *touches the ratepayer* in all the daily matters of life Public health, relief of the poor, the duties of county councils, lunatics, education, and midwives all come under its ægis As regards metropolitan pauperism it is somewhat disquieting to be told that the total expenditure for this purpose out of the rates, excluding the expenditure of the Metropolitan Asylums Board, is 15*s* 0¼*d* per head of the estimated population in the middle of the year 1901 When we consider in addition to this enormous sum the amount of money annually given for charitable purposes the cost of relief of the poor seems abnormally high With regard to vaccination the report on p 181 draws attention to the following —

> During the year an important decision was given by the High Court of Justice in an appeal from a conviction by the magistrates of

---

[1] THE LANCET, Jan 10th, 1903 p 117

[1] THE LANCET, Sept 19th (p 839) Oct 3rd (p 972) and 17th (p 1111), 1903

Leicester. In the case stated by the magistrates two questions were raised, viz., (1) whether the vaccination officer, by virtue of his appointment as such, [illegible] or special from the guardians at any time, [illegible] guardians' directions not to prosecute [illegible] could institute the proceedings which were taken against the appellant under the Vaccination Acts 1867 to 1898; and (2) whether it was a condition precedent to a prosecution by the vaccination officer under Section 29 of the Vaccination Act, 1867, that due proof should be given of service on the parent of the child by the public vaccinator of the notice mentioned in the Vaccination Acts, 1867 to 1898, and of his having visited the house of the child as therein directed. The court decided the first of these questions in the affirmative and as regards the second they held that such formal proof was not necessary in every case and they dismissed the appeal with costs.

The Local Government Board upon this decision being given drew the attention of the several boards of guardians and vaccination officers to it by means of a circular dated Sept. 2nd, 1902.

That portion of the report which deals with the working of the Sale of Food and Drugs Act is of extreme interest. As regards milk, which is the food-stuff most frequently adulterated, 11·6 per cent. of the samples taken during 1902 were found to be adulterated, this being the highest rate of adulteration recorded in any year since 1893. Many analysts call attention in their reports to the growing practice of reducing the quality of good milk so that it may just reach the standard fixed by the Board of Agriculture in its regulations for the sale of milk. The analyst for the county of Kent remarks that "this reduction is nowadays done very accurately." We long ago anticipated that the introduction of a limit in regard to the amount of fat would tempt the milk-seller to dilute rich milk down to the standard. It is difficult to see how the law can be made to reach those persons who adopt such a niggardly practice. If only the analyst were able to differentiate added water from the natural water of the milk there would, of course, be no need for standards at all. The difficulty is increased by the fact that poor milk, showing slightly less than 3 per cent. of fat, is occasionally the genuine product of the cow, but this is generally due to indifferent feeding or to ill-health. We believe that the limit of 3·25 per cent. of fat which the departmental committee appointed by the Board of Trade originally suggested fairly represents the milk of mixed herds and that the honest milk-dealer would have no difficulty at all in supplying milk well up to that standard. Sometimes also the fraud is gross. We are personally acquainted with an instance in which a family took a house in Kent for the summer. Cream was ordered from the local milkman. He supplied the cream, it is true, but he skimmed it off the milk supplied to the family. This skim-milk was charged as milk, the cream, of course, being charged for as cream in addition. The report draws attention to the fact that some magistrates think lightly of these offences. The analyst for Walsall states that he condemned a sample of milk because it contained 7 per cent. of added water, but the magistrate, without hearing the defence, dismissed the case with the remark that it was a paltry prosecution. We have always maintained that the penalties for offences connected with food-supply, whether in the form of adulteration or of selling putrid or diseased meat or other food-stuffs, are grossly inadequate and we are glad to find the following passage in the report, p. clxxiv.: "During the year we drew the attention of the Secretary of State for the Home Department to the fact that we have from time to time received complaints from local authorities respecting the inadequacy of the penalties imposed by justices for breaches of the provisions of the Sale of Food and Drugs Acts and he subsequently addressed a circular letter to clerks of the justices of the petty sessional divisions throughout the country asking that the matter might be brought to the notice of the justices in order that they might give special consideration to the question whether the penalties imposed in the cases coming before them were such as would be likely to deter offenders from repeating, and other persons from committing, the offence." During the year with which the report deals penalties were imposed in 2928 cases and in 164 of these the fine did not exceed 2*s.* 6*d.*, 77 being of 1*s.* and under. Punishment on this scale is simply ridiculous and worse than useless. London as usual shows a comparatively high rate of adulteration of milk, the percentage being 15·6 as against 10·3 in the 20 next largest towns of England and Wales. In six of the metropolitan boroughs the proportion exceeded 20 per cent. A large number of samples of margarine were reported to contain water, some in so great a proportion as 20 per cent. The analyst for Kent remarks upon this: "Water is not intrinsic to margarine; every drop we find in it has been put there with the sole purpose of its being sold at the price of margarine."

As regards the water-supply Dr. T. E. Thorpe sends in a long and valuable report (p. 213 *et seq.*). The Kent Company as usual stands at the head of the list of metropolitan water companies for general excellence of the water supplied. The district of the metropolis supplied by the Kent Company is served with water coming from 19 wells in the chalk. This water, though of great purity as regards organic contamination, is very hard. By Table K, which appears on p. 290, we see that the mean of degrees of hardness (one degree equals one part of carbonate of lime or its equivalent in 100,000 parts of water) for the year 1902 was 28·8 per cent. For the month of September the figure was 32·4. It seems to us that a company which in 1902 paid a dividend of 15 per cent. (*vide* p. cxcvi.) should be compelled to soften its water before delivery. Water of the hardness of over 20 per cent. is not always conducive to health as a beverage and is a constant source of expense when used for domestic purposes, both by making an extravagant quantity of soap necessary and by blocking hot-water apparatus.

MEDICAL MAYORS.

THE following have been elected or re-elected to the mayoral chairs of their respective boroughs:—

Bridport.—Mr. S. J. Allden, M.D. Durh., L.R.C.P. Lond., M.R.C.S. Eng., received his medical education at the University of Durham and St. Thomas's Hospital. In 1888 he took the degrees of M.B., B.S., and in 1890 the degree of M.D. Durh. In 1889 he was appointed house surgeon at the Royal Infirmary, Newcastle-on-Tyne, and during the four following years filled different resident appointments at the Hospital for Consumption and Diseases of the Chest at Brompton, London. He has been a member of the Bridport town council for six years, during which time he has filled the office of chairman of the sanitary committee.

Cambridge.—Mr. J. H. C. Dalton, M.D., D.P.H. Cantab., graduated in arts (twelfth wrangler) in 1884 and in the following year registered as a medical student. In 1889 he became a Licentiate of the Society of Apothecaries and in 1890 graduated as bachelor of surgery at Cambridge. Previously to taking the L.S.A. Dr. Dalton studied at St. Mary's Hospital. In 1893 he took the M.D. degree at Cambridge and subsequently the D.P.H. of that University. In 1890 he was elected guardian of the parish of Camberwell and two years later became a manager of the Metropolitan Asylums Board. After travelling round the world he settled at Cambridge where he was elected on the board of guardians in 1898 and member of the borough council in 1899 and an alderman in 1900. In 1902 he was elected chairman of the board of guardians.

Dartmouth.—Mr. R. B. Searle, L.R.C.P. Lond., M.R.C.S. Eng., was educated at King's College, London, where he distinguished himself in mathematics and medicine. He has been in active practice for more than 40 years. He was elected at the head of the poll as town councillor of Dartmouth six years ago. His term of office having expired three years ago he did not seek re-election but this year he was called upon by the town council to become their mayor.

Denbigh.—Mr. David Lloyd, M.B., M.S. Glasg., was educated at the University of Glasgow and the Middlesex Hospital, London. He is a justice of the peace and has acted as county councillor for four years.

Dorchester.—Mr. E. W. Kerr, M.D., M.Ch. Dub., was born in 1849 at Grange Gorman, near Dublin. He was educated at Dungannon Royal School and Trinity College, Dublin, and studied medicine at the School of Physic, at Sir Patrick Dun's Hospital, and at the Richmond and Whitworth Hospital. He graduated B.A., M.B., and M.Ch. in 1872 and M.D. in 1889 and became L.M. K. & Q.C.P.I. in 1872. Before going to Dorset in 1884 he practised in Donegal and Leitrim. For the past six years he has been on the Dorchester town council and served on several committees. He has been chairman of the recreation and reception committee and vice chairman of the sanitary committee for the past two years.

Falmouth.—Mr. William Banks, M.B. Lond., M.R.C.S.

Eng. (re elected), entered the council in 1892 on the extension of the borough and was elected alderman in 1898.

Hampstead.—Mr. Edward Collingwood Andrews, M.D. Cantab., M.R.C.S. Eng., son of Dr. James Andrews of Hampstead, was educated at University College School, St. John's College, Cambridge, and Guy's Hospital, London. He matriculated at the University of London in the honours division and proceeded to the B.Sc. degree in 1882 He was successively exhibitioner and foundation scholar of St. John's College and took the B.A. degree in 1884, having obtained honours in the natural science tripos, Parts I. and II. He obtained the degrees of M B, B.C. in 1886, M A. in 1887, M.D. in 1892, and the Membership of the Royal College of Surgeons of England in 1885. He entered the borough council of Hampstead on its formation in 1900 and was forthwith appointed chairman of the public health committee and on expiration of two years' term of office chairman of the housing committee. At the recent election he was returned at the head of the poll for the central ward.

Hedon.—Mr. James Soutter, M R C.S., L R C.P. Lond. (re-elected).

Honiton.—Mr. James Campbell Macaulay, M R C S. Eng., L.S A, who has been re-elected mayor of Honiton, has occupied the civic chair on five previous occasions—namely, in 1884, 1887, 1894, 1901, and 1902 He was for many years a member of the Honiton borough council but in 1897 he resigned his seat as alderman.

Saffron Walden.—Mr Henry Stear, M.R C S. Eng., L S.A. (re-elected), commenced his professional career in 1845 by serving for five years an apprenticeship to the late Mr Thomas Lucas of [illegible] a course of [illegible] ow and also one of chemistry at Cambridge, afterwards becoming a student at the Middlesex Hospital. He became a resident of Saffron Walden in 1854 and retired in 1895 after having been in practice for 41 years. He has always taken an active part in everything that tended to promote the welfare and interests of his fellow townsmen. He entered the town council in 1863 and retired after holding the office for three years but entered the council again five years ago

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Nov. 12th, Mr. JOHN TWEEDY, the President, being in the chair.

Diplomas of Membership were issued to 102 candidates.

It was referred to the Court of Examiners to consider, and to report upon, the remarks made by the visiting inspectors of the General Medical Council with respect to the final examination in surgery of the Conjoint Board.

A report was received from the delegates of the two Royal Colleges regarding the proposed conference with the General Medical Council in reference to the requirements of the Conjoint Examining Board in England respecting study and examination in chemistry, physics, and biology. The report was adopted but any action in reference thereto will depend on its adoption by the Royal College of Physicians.

The Council then considered the report of the Conjoint Committee on the regulations relating to the first examination and the first year of study. It was entered on the minutes and the recommendations contained in it were adopted subject to any modifications which may appear desirable after consultation with the medical schools and examiners.

The recommendations referred to are as follows:—

1. That Part I. Chemistry, Part II. Physics, Part III. Biology, and, at the option of the candidate, Part IV. Practical Pharmacy, be the subjects of the first examination.

2. That a minimum length of courses be required in chemistry, physics, and biology before candidates are admitted to examination in these subjects [illegible]

[illegible]

In physics 120 ,, ,, ,,
In biology 120 ,, ,, ,,

4. That these courses need not run concurrently, nor be completed within one year.

5. That these courses may be commenced or attended before the required preliminary examination in general education is passed.

6. That study at an institution other than a recognised medical school be counted for not more than six months of the curriculum.

7. That the study of anatomy and physiology be not recognised until after the first examination in chemistry, physics, and biology has been passed.

8. That no student be admitted to examination in medicine and [illegible] y after [illegible] owards [illegible] unted,

A letter was read from Mr. L. A. Bidwell, F.R C.S, dean of the Post-graduate College of the West London Hospital, applying for the recognition of that hospital as an institution where graduates of four years' standing may pass the necessary year of post-graduate study before presenting themselves for the final Fellowship examination. The letter was referred to the Court of Examiners.

The PRESIDENT stated that the Bradshaw Lecture would be delivered by Mr. Henry Morris on Wednesday, Dec. 9th, at 5 P.M., and that the subject of the lecture would be Cancer and its Origin.

The PRESIDENT reported that on Nov. 3rd he attended the ceremony of the laying of the foundation stone of King Edward VII. Sanatorium for Tuberculosis at Lord's Common, near Midhurst, and that after the ceremony he had the honour of being presented to His Majesty.

The SECRETARY reported the notices of motion for the annual meeting of Fellows and Members on Thursday, Nov. 19th.

PUBLIC HEALTH IN BOMBAY IN 1902.

THIS interesting report[1] includes those of the medical officers in charge of the hospitals for infectious diseases. The statistics are based upon the census return of 1901. The birth rate of the city is shown as 6209 more than the average of the preceding five years and is a birth-rate of 22·67 per 1000 against 17·42 during 1901; from this it will be inferred that there has been a marked improvement in the registration of births (the new scheme of registration of births and deaths proposed by Dr Turner has been in operation during the year). The mortality during the year under report was the lowest of any year since 1898.

The following is the list of the deaths from each zymotic disease during 1901 and 1902:—

	1901.	1902.
Plague	18,736	13,820
Cholera	193	75
Small pox	159	288
Measles	67	642
Whooping cough	97	83
Enteric fever	62	89
Remittent fever	7,266	3,847
Relapsing fever	1,560	651
Malaria ague	490	483
Dysentery	1,341	1,377
Puerperal fever	514	477
Simple continued fever	113	99
Total	30,593	21,931

The mortality from plague began its seasonal rise in January and reached its maximum on April 3rd and then declined. There was a decrease in the number of deaths from plague in all communities except Europeans and Negro-Africans, and there occurred a marked reduction in deaths from this malady in all sections of the city except Upper Colaba, Fort, Southern, and Chaupati. From August the plague mortality rose gradually to the end of the year. In the beginning of the year plague measures were carried out by the military officers appointed by the Government under the supervision of the health officer, subject to the control of the municipal commissioner, but by the end of March all the military officers had been withdrawn and the entire control of the plague administration was vested in the health department. This change was a desirable one inasmuch as now the influences affecting the health of the city come under the direct control of the health officer. The Government has, after careful consideration, done away with the compulsory measures and introduced voluntary ones directing the health department to follow a persuasive policy. Inoculation is not in favour with the people; the inhabitants of Bombay seem to have lost all faith in the protective effects of the prophylactic

During the year 288 deaths from small-pox occurred, as compared with 159 in 1901. *The increase is accounted for* by the number of unvaccinated people who went to Bombay from the Portuguese territories, most of whom soon after their arrival were found to be suffering from the disease. Cholera did not assume an epidemic form during the year.

---

[1] Annual report of the Executive Health Officer for the City of Bombay for the year 1902. By John A. Turner, M.B Edin, D P.H. Cantab., Executive Health Officer. Bombay, June, 1903. Pp. 113.

A total of 4518 deaths was registered from fevers. Remittent fever claimed the highest number—viz., 3847—being 3419 less than in the previous year and 1938 less than the average of the preceding five years. To enteric fever 89 deaths were ascribed, being 27 more than during the previous year and 42 more than the average of the last five years. 483 deaths were registered as due to ague, three more than during the previous year and 190 more than the average of the last five years. It was noted that the mortality from fever rose and fell with the mortality from plague. During the year investigations into the prevalence of malarial fever were made and a report was submitted to the corporation. The divisional health officers instructed their staffs in the methods of distinguishing the various mosquitoes and larvæ and a list of places was made out where anopheles larvæ were found. The anopheles culicifacies and anopheles Listonii are said to be the only malaria-bearing mosquitoes known in Bombay at present. The extracts from the health officer's report to the municipal commissioner show that sound advice is being given as to the best known means of preventing the breeding of anopheles.

Measles prevailed in an epidemic form during the last two months of the year and was accountable for 642 of the registered deaths. The corporation, having called for an exhaustive report on the question of the high infantile mortality in the city—(1) as to the causes and (2) on the measures and remedies for reducing it—the health officer in his letter on the subject to the municipal commissioner stated that the first point is a simple one to deal with and that on the second point it is not difficult to offer suggestions, but he expressed grave doubts as to whether the corporation can undertake to give practical effect to some of them. He observes that to suggest remedies for the apparent causes it is necessary to inquire into the conditions which predispose to these diseases. The statistics prove that the greatest mortality is amongst the poorer classes and the causes of this predominance are : (1) want of stamina in the mother ; (2) the hard work that mothers have to do during pregnancy ; (3) want of proper nourishment to infants ; (4) want of proper clothing ; (5) want of medical treatment in sickness ; (6) insanitary surroundings ; (7) overcrowding ; (8) insanitary dwellings ; (9) drugging of children to enable the mothers to attend to their work ; and (10) early marriage.

We are glad to note that seven additional dispensaries have been provided by the municipality and that the ten dispensaries have done excellent work during the year. The voluminous statistical tables are carefully drawn up and the "Diagram-Weekly Total and Plague Mortality" shows at a glance the weekly total mortality, the weekly plague mortality, and the weekly average mortality ; other useful illustrations exhibit the incidence of plague and cholera in different parts of the city.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of this College was held on Nov. 3rd, Dr. T. S. CLOUSTON, the President, being in the chair.

The PRESIDENT referred in feeling terms to the lamented death of Dr. G. W. Balfour, the fourth Fellow on the roll of attendance, President in 1882–84, librarian and trustee for many years, and one who took the keenest interest in all the affairs of the College. His death was a loss alike to the College and to the profession of medicine.

John Cumming, F.R C.P., F.R C.S Edin., Percy Theodore Herring, M.D., F.R C.P.Edin., and John William Simpson, M.B., C.M., F R C.P.Edin., were introduced and took their seats as Fellows of the College The following Members were admitted by ballot to the Fellowship of the College : James Taylor Grant, M.B., C M., M.R.C.P. Edin., Edinburgh ; Charles Cromhall Easterbrook, M D., M.R.C.P. Edin., Glengall-by-Ayr ; and Edwin Bramwell, M B., C.M., M R C.P. Edin., Edinburgh. The following candidates were *admitted to the Membership of the College after examination* : George Lyon, M.B., Ch.B Edin., Edinburgh ; Frederick Norton Menzies, M.B., Ch.B. Edin., London ; and Alexander Lyons, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Torquay. The Registrar reported that since the last quarterly meeting 40 persons had obtained the Licence of the College by examination.

Dr. A. R. Simpson has been nominated trustee of the College in room of the late Dr. Balfour. Dr. J. Playfair has been elected as representative on the conjoint committee of the triple qualification.

MEDICINE AND THE LAW.

The Traffic in the Streets of London.

IN a letter appearing in the *Times* of Oct 28th attention was called to the ill-paved, ill-lighted, and unprotected condition of the roads surrounding the Albert Hall, where conditions are observable which are surprising in such a locality, and in another letter upon the same date the employment of heavy traction engines drawing trucks through the streets of London was criticised and it was urged that county and borough councils should have increased powers to regulate their use. The conditions of London traffic impose a certain amount of danger of accident upon all who circulate in the streets of the metropolis and it is important that such danger should be reduced to a minimum, while it is also desirable from the point of view of the public health that the greatest possible degree of cleanliness and quiet consistent with the busy life of a great city should be obtained. The insanitary and unsafe state of the roadway near the Albert Hall is a matter of detail with regard to which concert-goers and those who live in the neighbourhood might well combine in order to make their protests heard, but it is not a solitary instance and in spite of modern progress and of improvement in many directions London is not, and apparently never will be, a well-paved, well-lighted city with its streets watched by a police force proportionate to its requirements. To take conspicuous examples, Regent-street and Oxford-street have been subjected to patching operations during the past year but in both of these important thoroughfares the roadway is in places in a condition which renders it not only filthy in wet weather but at all times dangerous to horse traffic. Less frequented streets are often in no better state and in the majority of our quiet squares and unimportant thoroughfares such safety as there is at night or on foggy afternoons is due to the law-abiding character of the people rather than to the deterrent effects of light and supervision. With regard to the traction-engine nuisance the demolition and rebuilding of whole streets, coupled with tunnelling for the purposes of underground railways have made trains of heavily laden trucks part of the regular traffic of London streets, visible by day and painfully audible by night. The Locomotives Act, 1898, enabled county and borough councils to permit the loading of wagons drawn by engines of necessarily increased weight with burdens exceeding those which were previously permitted and provided generally for a heavier locomotive traffic upon our highways, and the new state of affairs shows a tendency to become unpleasantly obtrusive. In addition to its effect upon the roadway and to the disturbance caused by noise and vibration, the traction engine with its train behind it appears to have increased the pace at which it travels and the man who should be present as a protection to those driving horses is not always conspicuous when an occasion for his intervention arises. The hardship which presses upon the individual in these circumstances lies in the fact that whatever benefit may accrue to the community he is without compensation for any injury which he may personally sustain. He cannot sue the owner of the traction engine for broken rest or for shaken nerves. If his horse is frightened he is not likely to be able to establish negligence that will entitle him to damages and if his house suffers he is still less likely to obtain satisfaction. That Londoners are beginning to protest is not to be wondered at. The popularity and usefulness of the motor-car have perhaps helped to encourage the idea that the horse may advantageously be dispensed with and that mechanical modes of traction should be encouraged but it will be a matter for considerable regret if the motor-car and the traction engine are allowed to become continual sources of irritation and danger to the vast majority who do not use either of them.

The Peculiar People

An inquest held at West Ham recently showed, what, indeed, hardly needed demonstration, that the law can do nothing to save the lives of foolish people from being sacrificed to their own folly The deceased, according to the medical evidence, died from pleurisy and bronchitis The medical practitioner who had made a post mortem examination had also been called in to see her before death and had prescribed Other evidence showed that the deceased had told the witness who had summoned the medical man that she had better put his medicine down the sink and had prevailed upon her to do so The coroner expressly asked whether any member of the sect of Peculiar People, to which she belonged, had prevailed upon the deceased to dispense with medical aid, but this was denied An elder of the sect had been called in and had prayed over the sick woman but there was nothing to show that he could in any way be made liable for her death The matter, therefore, was concluded by a verdict of the jury in accordance with the medical evidence

Medical Galvanism

THE following cases[1] are given by M Bailly, physician to the Hôpital de la Pitié, and M Meyranx, in an article on a new mode of applying galvanism to the cure of painful affections of the joints and nerves, in the last number of the *Archives Générales*

Chorea cured by Galvanism

A girl, after difficult dentition, was affected with convulsions of the muscles of the right cheek, which soon extended to the shoulder of the same side The disorder had resisted all the treatment which had been employed, and at the age of seven years the symptoms had become more violent When she was brought to La Pitié, she was in a debilitated state, the muscles on the right side were much wasted, the alternate contraction and relaxation of the muscles in the face produced constant convulsions and distortions Galvanism was first applied to this patient by simple communication, without the introduction of needles, but she derived no benefit from it, a needle was then introduced near the first and second cervical vertebræ and another was placed near the division of the brachial plexus Three elements developed enough of the galvanic fluid to produce decided contractions and a painful sensation The girl felt so much relieved by the operation, that the next day she asked to be galvanised again, but as we happened to touch, by mistake, with the thread which served as a conductor to the negative fluid, an element at a great distance from the first element, she felt so great a shock, and such severe pain, that the needles were torn out from their situation, and we had considerable difficulty in persuading her to place herself again in the galvanic circle The operation was prolonged for half an hour, and six sittings sufficed to cure, completely, a disorder which had for years resisted the most powerful remedies that could be employed

Messrs Bailly and Meyranx state, that galvanism, combined with acupuncturation, had been employed with the most decided success in a great number of cases, the details of which they intend shortly to lay before the public The pain produced by the operation is inconsiderable, and the galvanic fluid possesses the singular property of never inflaming the part which it penetrates What then, they exclaim, is the nature of this fluid which burns and melts metals, which puts charcoal in a state of incandescence, and which traverses the living tissues of the body, in which it increases sensibility and contractility in so marked a manner, without leaving a trace of disturbance behind it? The phenomena are altogether inexplicable

---

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8391 births and 5169 deaths were registered during the week ending Nov 14th The annual rate of mortality in these towns, which had been 15 1, 15 8, and 16 1 per 1000 in the three preceding weeks, further rose last week to 17 9 per 1000 In London the death rate was 16 7 per 1000, while it averaged 18 4 in the 75 other large towns The lowest death rates in these towns were 6 0 in Hornsey, 7 4 in King's Norton, 7 9 in Aston Manor, 10 2 in Hastings, 10 3 in Grimsby, 10 7 in Croydon and in Willesden, and 10 8 in Walthamstow and in Brighton; the highest rates were 22 9 in Nottingham, 23 5 in Wigan, 23 9 in Leeds, 25 3 in Salford, 25 8 in Rochdale, 26 8 in Sunderland and in Tynemouth, 26 9 in Middlesbrough, and 32 2 in Warrington The 5169 deaths in these towns last week included 432 which were referred to the principal infectious diseases, against 532, 523, and 419 in the three preceding weeks, of these 432 deaths, 138 resulted from diarrhœa, 79 from measles, 61 from diphtheria, 59 from "fever" (principally enteric), 51 from whooping cough, 43 from scarlet fever, and one from small pox. No death from any of these diseases was registered last week in Hornsey, Tottenham, Bournemouth, Devonport, Burton-on Trent, Wolverhampton, King's Norton, Coventry, Stockport, Bury, Barrow in Furness, West Hartlepool, or South Shields, while the highest death rates from the principal infectious diseases were recorded in Hanley, Wigan, Warrington, Preston, Rotherham, York, Sunderland, Gateshead, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Warrington, Blackburn, Rotherham, York, and Sunderland, from scarlet fever in Wigan; from diphtheria in Hanley, from whooping-cough in Warrington, York, and Newport (Mon), from "fever" in Bolton and Merthyr Tydfil, and from diarrhœa in Northampton, Preston, and Gateshead One fatal case of small pox was registered last week in London, but not one in any of the 75 large provincial towns The Metropolitan Asylums hospitals contained 51 small pox patients on Saturday last, Nov 14th, against 34, 42, and 43 on the three preceding Saturdays, 16 new cases were admitted during last week, against 26, 12, and five in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 1858, 1828, and 1854 at the end of the three preceding weeks, had declined again to 1824 at the end of last week, 185 new cases were admitted during the week, against 209, 199, and 224 in the three preceding weeks The deaths referred to pneumonia and diseases of the respiratory organs in London, which had been 194, 260, and 271 in the three preceding weeks further rose last week to 339, and were seven above the number in the corresponding period of last year The causes of 49, or 1 0 per cent, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Bristol, Leicester, Salford, Bradford, Leeds, Newcastle on Tyne, and in 47 other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, St Helen's, Sheffield, Middlesbrough, Sunderland, South Shields, and Gateshead

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 16 7, 17 0, and 15 8 per 1000 in the three preceding weeks, rose again to 17 4 per 1000 during the week ending Nov 14th, and was 0 5 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12 0 in Greenock and 13 9 in Perth, to 18 4 in Glasgow and 18 5 in Dundee The 571 deaths in these towns last week included 20 which were referred to diarrhœa ten to measles, ten to "fever," four to diphtheria, four to whooping cough, and one to small pox, but not one to scarlet fever In all, 49 deaths resulted from these principal infectious diseases last week, against 77, 62, and 53 in the three preceding weeks These 49 deaths were equal to an annual rate of 1 5 per 1000, which was also the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 39, 33, and 15 in the three preceding weeks, increased again last week to 20, of which seven occurred in Glasgow, four in Aberdeen, three in Edinburgh, three in Dundee, and two in Paisley. The deaths from measles, which had been 16, 11, and 19 in the three preceding weeks, declined again to ten last week and included nine in Glasgow. The fatal cases of "fever," which had been six, two, and one in the three preceding weeks, rose again last week to ten, of which five were registered in Glasgow, three in Dundee, and two in Edinburgh. The deaths from diphtheria, which had been five in each of the two preceding weeks, declined to four last week and included two in Glasgow and two in Edinburgh. The fatal cases of whooping-cough, which had been eight, seven, and six in the three preceding weeks, further decreased last week to four, of which two occurred in Glasgow, where the fatal case of small-pox also was recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 92, 108, and 107 in the three preceding weeks, rose again last week to 129, but were ten below the number in the corresponding period of last year. The causes of 19, or more than 3 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·5, 21·2, and 21·7 per 1000 in the three preceding weeks, declined again to 20·9 per 1000 during the week ending Nov. 14th. During the past four weeks the death-rate has averaged 21 3 per 1000, the rates during the same period being 15 9 in London and 15·8 in Edinburgh. The 152 deaths of persons belonging to Dublin registered during the week under notice showed a decline of six from the number in the preceding week and included seven which were referred to the principal infectious diseases, against 13, seven, and two in the three preceding weeks; of these, three resulted from whooping-cough, three from "fever," and one from scarlet fever, but not any from small-pox, measles, diphtheria, or diarrhœa. These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 1·3 in Edinburgh. The three fatal cases of whooping-cough exceeded the number recorded in any recent week. The deaths from "fever," which had been three, four, none, and one in the four preceding weeks, increased last week to three. The 152 deaths in Dublin last week included 32 of children under one year of age and 47 of persons aged 60 years and upwards; the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a marked excess. Six inquest cases and three death from violence were registered, and 50, or about one-third, of the deaths occurred in public institutions. The causes of eight, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1903

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·8 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In the three preceding months the rates had been 6·4, 5·5, and 6·5 per 1000 respectively. The rates were considerably below the average in Kensington, Chelsea, the City of Westminster, Hampstead, Holborn, and the City of London, while they showed the largest excess in St. Pancras, Hackney, Bethnal Green, Stepney, Poplar, and Deptford. There was a slight increase last month in the prevalence of small-pox; of the 40 cases notified during the month 19 belonged to Southwark, five to the City of Westminster, four to Lambeth, and two each to St. Pancras, Stepney, and Wandsworth. The Metropolitan Asylums hospitals contained 42 small-pox patients at the end of last month, against 66, 57, and 21 at the end of the three preceding months; the weekly admissions averaged 10, against 15, nine, and five in the three preceding months. Scarlet fever was less prevalent during October than it had been in the preceding month; the greatest proportional prevalence of this disease occurred in St. Pancras, Bethnal Green, Stepney, Poplar, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1697, 1754, and 1849 at the end of the three preceding months, had declined again to 1794 at the end of last month; the weekly admissions averaged 210, against 234, 211, and 241 in the three preceding months. The prevalence of diphtheria showed a slight increase last month as compared with the preceding month. Among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Poplar, Southwark, Battersea, Deptford, and Greenwich. There were 753 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of October, against 840, 716, and 671 at the end of the three preceding months; the weekly admissions averaged 121, against 130, 94, and 114 in the three preceding months. The prevalence of enteric fever, which had shown a continuous increase during the preceding six months, further rose last month; the greatest proportional prevalence of this disease was recorded in Hackney, Finsbury, the City of London, Shoreditch, Stepney, and Battersea. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 119, 172, and 247 at the end of the three preceding months, had further risen to 285 at the end of last month; the weekly admissions averaged 44, against 18, 27, and 40 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Holborn, Finsbury, Bethnal Green, Stepney, and Bermondsey. The 20 cases of puerperal fever notified last month included five in Hackney and two each in Kensington, Chelsea, Lambeth, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Oct. 31st the deaths of 5183 persons belonging to London were registered, equal to an annual rate of 14·6 per 1000, against 12 5, 13·5, and 14 4 in the three preceding months. The lowest death-rates in London last month were 8·9 in Hampstead, 10·0 in Stoke Newington and in Lewisham, 10·6 in the City of London, 11·3 in the City of Westminster, and 12·0 in Wandsworth; while the highest rates were 18·6 in Bethnal Green, 19·0 in Bermondsey, 19·3 in Finsbury and in Shoreditch, 20 8 in Stepney, and 21 1 in Poplar. The 5183 deaths from all causes included 629 which were referred to the principal infectious diseases; of these, 62 resulted from measles, 30 from scarlet fever, 54 from diphtheria, 38 from whooping-cough, 49 from enteric fever, and 396 from diarrhœa. No death from any of these infectious diseases was recorded last month in Hampstead; in the other boroughs they caused the lowest death-rates in Kensington, Hammersmith, Chelsea, Islington, the City of London, and Lewisham; and the highest rates in Fulham, Holborn, Finsbury, Bethnal Green, Stepney, Poplar, and Bermondsey. The 62 fatal cases of measles showed a decline of 24 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Fulham, St. Marylebone, Stepney, Lambeth, and Wandsworth. The 30 deaths from scarlet fever were 38 below the average number in the corresponding periods of the ten preceding years; the highest proportional mortality from this disease occurred in Hackney, Bethnal Green, Poplar, and Wandsworth. The 54 fatal cases of diphtheria were only about one quarter of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, St. Marylebone, St. Pancras, Stepney, Poplar, and Greenwich. The 38 deaths from whooping-cough showed a decline of 32 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Fulham, St. Pancras, Bermondsey, Battersea, Deptford, and Greenwich. The 49 fatal cases of enteric fever were 28 below the corrected average number; among the various metropolitan boroughs the highest "fever" death rates were recorded in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Battersea. The 396 deaths from diarrhœa were 180 in excess of the average; this disease was proportionally most fatal in Holborn, Finsbury, Bethnal Green, Stepney, Poplar, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 13 per cent. above the average.

Infant mortality in London during October, measured

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING OCTOBER, 1903.

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated population in the middle of 1903.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.

* Including membranous croup.

by the proportion of deaths among children under one year of age to registered births, was equal to 155 per 1000 The lowest rates of infant mortality were recorded in Chelsea, St. Marylebone, Hampstead, Islington, Camberwell, and Lewisham; and the highest rates in Finsbury, the City of London, Shoreditch, Bethnal Green, Stepney, and Poplar.

THE SERVICES.

Royal Navy Medical Service.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Michael Joseph Smith has been allowed to withdraw from His Majesty's Naval Service with a gratuity

Deputy Inspector-General of Hospitals and Fleets Edward Elphinstone Mahon, C.B, has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Oct. 10th, 1903).

The following appointments are notified:—Staff Surgeon G. T. Collingwood to the *Berwick*. Surgeons: A. J. Wernet to the *Berwick* and H. A. Julius to the *Cambridge*.

Army Medical Service.

Surgeon-General G. J. H. Evatt, C.B., is placed on retired pay (dated Nov. 11th, 1903).

Royal Army Medical Corps.

Major W. Moyle O'Connor, R.A.M.C. (Militia), assumes medical charge of women and children, Wellington Lines, Aldershot.

Surgeon-General James Albert Clery, C.B., joins at Salisbury for duty as Principal Medical Officer, 2nd Army Corps, in place of Surgeon-General G. J. H. Evatt, retired. Lieutenant Colonel Andrew Baird, retired list, late Royal Army Medical Corps, is appointed to the medical charge of troops at Worcester.

Army Medical Reserve of Officers.

Surgeon-Lieutenant A. L. Jones to be Surgeon-Captain, with precedence next below J. P. S. Ward (dated Nov. 11th, 1903).

Surgeon-Major G. D. P. Thomas having resigned his Volunteer appointment ceases to be an officer in the Army Medical Reserve of Officers. Surgeon Major H. Wright having resigned his Volunteer appointment ceases to be an officer in the Army Medical Reserve of Officers.

Imperial Yeomanry.

Lovat's Scouts: Surgeon-Lieutenant J. R. Kennedy resigns his commission (dated Nov. 14th, 1903).

Scottish Horse: The appointment of David Mitchell Macdonald to be Surgeon-Lieutenant, which was announced in the *London Gazette* dated Oct 23rd, 1903, is cancelled; Surgeon-Lieutenant David Mitchell Macdonald, from 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders), to be Surgeon-Lieutenant (dated Oct. 24th, 1903).

Volunteer Corps.

Royal Engineers (Volunteers): 1st Devonshire and Somersetshire: Surgeon Captain J. Fuller to be Surgeon-Major (dated Nov. 14th, 1903) 2nd Lancashire (the St Helens): Surgeon-Lieutenant E. H. Monks to be Surgeon Captain (dated Nov 14th, 1903).

Rifle: 2nd Volunteer Battalion the Lincolnshire Regiment: Surgeon Captain S. H. Perry resigns his commission (dated Nov. 14th, 1903). 3rd Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Lieutenant Colonel R A Prichard resigns his commission and is granted the honorary rank of Surgeon Colonel, with permission to wear the uniform of the battalion on retirement (dated Nov. 14th, 1903) 1st Volunteer Battalion the Hampshire Regiment: Surgeon-Captain H M. Brownfield, from 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment, to be Surgeon-Captain (dated Nov 14th, 1903) 5th (Isle of Wight Princess Beatrice's) Volunteer Battalion the Hampshire Regiment: William Henry Harland to be Surgeon-Lieutenant (dated Nov. 14th, 1903) 2nd Volunteer Battalion the Essex Regiment: Surgeon Lieutenant J. E. Molson to be Surgeon-Captain (dated Nov 14th, 1903).

Royal Army Medical Corps (Volunteers).

The Glasgow Companies: William Bryce to be Lieutenant dated Nov. 14th, 1903).

Volunteer Officers' Decoration.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force who have been duly recommended for the same under the terms of the Royal Warrant (dated July 25th, 1892):—*North-Eastern District: Rifle:* 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Lieutenant John Hugh Maclean. 1st Volunteer Battalion the King's Own Yorkshire Light Infantry: Brigade-Surgeon-Lieutenant-Colonel Edwin Lee *North-Western District: Rifle:* 3rd Volunteer Battalion the Manchester Regiment: Brigade-Surgeon-Lieutenant-Colonel James Duncan. *Scottish District: Rifle:* 2nd Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Major Robert Thin Craig Robertson. *Woolwich District: Royal Army Medical Corps (Volunteers), the Woolwich Companies:* Major Charles Henry Hartt.

Reform in the French Navy.

Several minor reforms, all more or less bearing upon the health and well-being of the officers and men of the French navy, have recently been carried out under the auspices of M. Camille Pelletan, the Minister for that department. We append a brief account of these innovations compiled from the *Archives de Médecine Navale* for July. Formerly the punishments inflicted on sailors were largely at the discretion of commanding officers and consequently varied considerably in different vessels. In order to secure uniformity all offences are in future to be dealt with in accordance with an established system. The Bérenger law, which deals with first offences, has been made applicable in the navy; all entries relating to a first offence are to be erased from the offender's record of service provided he can pass a certain time without again committing himself. Under the old regulations men could be punished by the withholding of their wine ration; this clause has been suppressed, the Minister being advised that the deprivation was likely to exercise an injurious effect upon health. Soup instead of coffee can be drawn for breakfast by men who prefer it. The quality of the string which is used for tying roasting meat to the spits in naval kitchens is to be strictly supervised; the employment of tarred hemp or yarn for the purpose should be rigorously interdicted. Officers and men may in future be permitted to pass the night on shore as well as the day whenever their services can be dispensed with afloat. With the exception of the chapels attached to hospitals and prisons all establishments of this description are to be closed. Sailors desirous of taking part in public worship can attend the parish churches. Tobacco smoking is forbidden to all apprentices and boys in the navy. Finally, in all official correspondence the phraseology is to be as simple and direct as possible; the phrase "I have the honour" is specially interdicted.

Surgical Work in the Italian Navy.

The statistics of the surgical division of the Italian naval hospital at Venice for a period of 16 months from the beginning of September, 1901, to the end of December, 1902, form the basis for an interesting article in the *Annali di Medicina Navale* for September last, the author being Dr. Gaetano Tacchetti, chief medical officer of the second class. During the period 329 patients were treated with the following results: cured, 281; improved, 1; no improvement, 29; died, 1; and remaining under treatment, 17. The number of operations performed was 117, including laparotomy, resection of rib, radical cure of hernia (18), amputation (three), and disarticulation (two) Before commencing to operate Dr. Tacchetti succeeded in effecting the introduction of the antiseptic system throughout the whole establishment, taking as his model that in force in the Padua hospital. To the rigorous application of this system the highly satisfactory results are, no doubt, in a great measure due.

Deaths in the Services.

Lieutenant-Colonel Vivian Wearne, late of the Royal Army Medical Corps, at Spitzbergen, Jamaica, on Oct. 16th. The deceased officer, who was 62 years of age, joined the army as an assistant surgeon in March, 1865, was promoted to surgeon in March, 1873, to surgeon-major in February, 1878, and retired in February, 1886, with the rank of surgeon-lieutenant colonel.

The War Office has sanctioned the adoption of the site on Gun Hill, Aldershot, on which it is proposed to place an obelisk as a permanent memorial to all ranks of the Royal Army Medical Corps who fell in South Africa.

Correspondence.

"Audi alteram partem"

HETEROGENESIS

To the Editors of THE LANCET

SIRS,—Apart from the historical interest in the question of heterogenesis to which you allude in your issue of Nov 7th (p 1316), I think Dr H O Bastian's paper emphasises most profitably a much needed lesson There are many in this age of abstracts and epitomes who are compelled by circumstances to read conclusions and results rather than the experimental evidence on which they are based and the often intricate chain of reasoning by which they are supported The more active a man's mind the more diverse are the calls on his attention and the more impossible it becomes for him to do more than accept in many cases the manufactured article without actually examining for himself the complicated machinery by which it was produced This, it seems to me, gives a fallacious air of finality to many modern doctrines, and even on much controverted points many have to form their opinion more on the known attainments of the exponents of one or another rival theory than on a just estimation of the difficulties which may underlie the acceptance of either In this way, whoever, like Dr Bastian, calls attention to less commonly accepted views on any subject does good service by causing men to reflect on the bases of their conceptions and to remember that however widely a given view may be held its contrary has often never been absolutely disproved With regard to the details of Dr Bastian's paper I think it would be well carefully to mark the distinction between the origin of a *case* of disease *de novo* and the origin of a *cause* of disease *de novo* For example, in the case of a widely distributed organism like the tubercle bacillus no one will, I think, deny that cases of tuberculous disease may arise *de novo*, that is without direct contagion from a previous case In fact, the difficulty of accepting Behring's view of the long latency of the bacillus in the body lies in the impossibility of excluding a much later infection from an untraceable source, but all this does not disprove the possibility or even the probability of direct contagion in certain cases Dr Bastian argues that gland irritation from obvious causes *plus* a certain systemic condition is the real basis of the "scrofulous" disease of the glands and that tubercle bacilli are the "product" of this condition This may only be another way of stating the generally accepted fact that a certain "predisposition" *plus* infection is necessary to the production of these lesions, or, as Sir Dyce Duckworth puts it, that a person is first "strumous" and then becomes "tuberculous" But Dr Bastian goes on to state that he has proved the possibility of the origin of the tubercle or other bacilli *de novo* This apparently refers to Dowdeswell's experiments reported in 1884 Now, in the first place, these experiments were not made with pure cultures of micro organisms but with putrid blood and Dowdeswell himself remarks that "many microphytes of very various forms were observed in the blood under the microscope" Now "Davaine's septicæmia" was apparently, from Dowdeswell's description, produced by diplococcus or streptococcus whereas in "Pasteur's septicæmia the bacillus œdematis maligni was found Dr Bastian's theory that these were altered forms of the same organism is not *proved* by the experiments because pure cultures were not originally used Sir John Burdon Sanderson's experiment is quoted, however, to show the *de novo* origin of the bacillus of "Pasteur's septicæmia," but as this bacillus is found in the intestine all that it *proved* is that extensive damage to the peritoneum or in his words "the intensity of the inflammation," enabled the bacillus to migrate from its usual habitat into regions where it could exert its pathogenic properties In fact on p 1222 Dr Bastian says "Here we have the *de novo* production of a contagious disease , but on p 1223 he says "I, on the other hand, have proved the possibility of their (i e, the micro organisms) *de novo* origin "

It is now very rightly insisted upon that fallacies are likely to result if we base our views of disease in man too exclusively on the results of experimental investigations on animals, valuable as these are when due allowances are made But in spite of this I do not think it is fair to ignore entirely the results of the direct injection of tubercle bacilli in pure culture into animals and to base our view of the origin of tuberculous disease on a theory with which these results are incompatible Such a proceeding might, to quote Dr Bastian, bring the question of the etiology of tuberculous affections "more closely into accord with former views," but views as such are not more valuable when old than when new, and what is desirable is to bring our views into accord with facts, which if accurately ascertained are of perpetual value whether they be old or whether they be new.

That the soil is as important as the seed and that great variations in type and properties may obtain in various bacteria is admitted by all, but this does not mean that the soil can generate the seed or that it can even effect a gross variation in the kind of seed with which it is fertilised To suppose that the streptococcus pyogenes could by inoculation become the bacillus œdematis maligni would be indeed to gather the grapes of theory from the thorns of a most inconclusive experiment

I am, Sirs, yours faithfully,

J M FORTESCUE BRICKDALE, M A, M D. Oxon

Clifton, Nov 14th 1903

RECURRENT OVARIAN CYSTOMA AND ABERRANT ACCESSORY OVARIAN STRUCTURES.

To the Editors of THE LANCET

SIRS,—In THE LANCET of Nov 14th (p 1393) Mr W Roger Williams wrote that my explanation of the cases recorded in THE LANCET of Oct 31st "leaves something to be desired" and he maintained that the presence of aberrant accessory ovarian structures is "the cause of most of these curious phenomena" In the cases in question an ovarian tumour developed after the ovary was supposed to have been removed for cystic disease, and my conclusion was that the condition could "be *explained only* by assuming that a minute portion of ovarian tissue is inadvertently and perhaps unavoidably left in the body"[1] at the first operation In the next paragraph I stated that the impossibility of completely removing an ovary in some cases was demonstrated by the discovery of an accessory piece of ovarian tissue so close to the uterus that its removal was not possible unless the womb was taken away also I then related two cases in which I had found ovarian tissue close to the divided surface of the broad ligament when it was supposed that the ovary had been completely removed It seemed to me obvious that in these last cases the ovary had been divided and a small part of it had been left at the first operation simply because the surgeon (myself in one instance) had not tied the broad ligament sufficiently low It may be suggested that in these cases also there were accessory ovaries but in one of them the utero ovarian ligament was seen expanding into a piece of ovarian tissue of the normal shape of the adjacent part of the ovary and it is well known that it is often difficult to tie and to divide the broad ligament by the transfixion method so as to be sure of removing all the ovarian tissue I did not further attempt to differentiate between accessory ovaries and pieces of healthy tissue detached from normally shaped ovaries as the seat of origin of secondary non malignant growths

The occurrence of aberrant accessory ovarian structures is well known The late Mr Lawson Tait described them[2] 20 years ago, taking as his authority the works of Herman, de Sinéty, and Beigl He added that "it is possible that some of the cases of continued menstruation after the removal of both ovaries may have their peculiarity from some such cause as this " He suggested also that a patient with an accessory ovary "might have been the subject of a third ovarian tumour " There seems to be no doubt that this may occur and it is not unlikely that the presence of some detached fragment of ovarian tissue explains the case I briefly referred to in which I removed a multilocular cyst growing from the wall of the bladder But in the cases under discussion it does not seem to me more probable that accessory pieces of ovarian tissue existed than that a minute portion of healthy ovary was detached in enucleating the *first formed new growths* At none of the second operations was there anything to suggest that the tumours grew from a situation different from that of a deeply imbedded ordinary ovarian tumour. In the circumstances it seems to me incapable of proof that the tumours arose from accessory ovaries and it is equally impossible to demonstrate the absence of such aberrant pieces of ovarian tissue. Hence, although Mr. Williams has urged the importance of an interesting speculation which I only suggested, my statement that some portion of ovarian tissue was left behind is as comprehensive as the facts justify.

---

[1] THE LANCET, Oct 31st, 1933 p 1223 (last lines of page)

[2] Diseases of the Ovary, fourth edition, 1833 pp 9-10

Mr. Williams believes that accessory ovaries after removal of the main masses of ovarian tissue become centres of great formative activity and that "in these circumstances the limits of physiological activity may easily be overpassed, and when the process becomes pathological it eventuates in the formation either of non-malignant cystoma or a malignant tumour. Thus may be explained the extraordinary frequency of malignant disease after the removal of both ovaries." This involves the whole question of the origin of cancer and of tumours, which I do not propose to ask leave to discuss, but I should like to point out that there are cases in which it is indisputable that removal of the ovaries has been followed by remarkable improvement in recurrent malignant disease of the breast. Although the improvement is sometimes, possibly always, only temporary, yet the fact of its occurrence seems rather opposed to Mr. Williams's view.

I have long been of opinion that ovarian tumours are malignant more often than is generally supposed. When a malignant ovarian tumour is removed a recurrence follows, I think, invariably and a microscopic examination of the primary neoplasm often enables the surgeon to predict the development of secondary growths. In such cases malignant disease cannot be described as a consequence of removal of the ovaries, and apart from these cases my personal experience does not afford any data to support Mr. Williams's statement that there is an extraordinary frequency of malignant disease after removal of both ovaries.

I am, Sirs, yours faithfully,

Portman-street, W., Nov. 14th, 1903. JOHN D. MALCOLM

THE FUTURE OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—You are correct in saying I am unaware of the action taken by the medical staff in this matter for some years but that is my misfortune and not my fault. I have tried to obtain copies of the full evidence and reports submitted to the Mansion House Committee by members of the staff and medical council but without success, so you will see you are in error in supposing that because I am a governor I "surely could obtain access" to the various reports.

In my opinion no scheme will be supported by the public unless it has the almost unanimous approval of the medical council of the hospital. Yet the views of the staff have not been, and are not, properly and sufficiently considered at the meetings of the committees and governors and by the treasurer and officers. They have been practically ignored hitherto, with consequences of grave peril to St. Bartholomew's Hospital.

Both the press and the governors ought to be supplied with the complete memoranda containing the full evidence and reports which were printed for the Mansion House Committee. Had the governors had these documents before them they would probably not have voted as they did at the meeting of Nov. 5th.—I am, Sirs, yours faithfully,

Banbury, Nov. 16th, 1903. ANDREW MOTION.

To the Editors of THE LANCET.

SIRS,—Mr. Andrew Motion, who tells us in a letter in THE LANCET of Nov. 14th, p. 1392, that he is a governor of St. Bartholomew's Hospital, is evidently in the happy position of a man who has made a great discovery. For he, a governor of the hospital, has at last realised that if St. Bartholomew's Hospital had more land it could more easily erect more and better buildings than it can on its present site! And, like other similar discoverers, he is not satisfied with announcing his discovery, but proceeds to comment on the "supineness" of others who might have been expected to guide him in his search.

Thus—"One of the most remarkable features in this prolonged controversy has been the absence of any expression of opinion by the medical staff of the hospital." Again—"So long as the medical staff stands silent so long will there be doubt and mistrust" And once more—"Doubtless the views of the staff were officially submitted to the Mansion House Committee, *but they have never reached either the governors* or the general public." (The italics are my own.) Now, in view of the real facts which I will proceed to enumerate it is quite evident that Mr. Motion has been quietly asleep for some years and now that he has awakened he is quite oblivious of what has passed during his long slumbers. Sir H. Burdett's proposal to raise £600,000 and purchase additional land evidently appeals to him as a completely novel idea. Did he never hear of Sir Henry Knight's proposal to raise an almost similar sum for the very same purpose in 1901? It was fully placed before him as a governor! Did he support it then or not?

Here, Sirs, are some facts as to what the staff have actually done. They are beyond dispute and as they are known, or should be known, to every governor they are in no way secret, and have also been fully placed before the Lord Mayor and his committee. 1. Four years ago, on Nov. 2nd, 1899, a deputation of the medical council urged the treasurer and almoners to purchase the whole of the site of Christ's Hospital. They had previously sent in a full report of the seriously defective state of the casualty, out-patient, and special departments. 2. On August 22nd, 1901, when the purchase of a portion of Christ's Hospital was more imminent, the staff sent a printed circular letter *to every governor*, signed unanimously by every member of the medical council, summarising their previous actions alluded to above, and detailing at great length the need for more land and new buildings. In this letter they said, "In our opinion the whole site of Christ's Hospital ought to be obtained, and we desire to impress the importance of the statements we have made on every governor. ...... To lose this present opportunity of obtaining the whole site is to prevent the growth and limit the sphere of action of a noble charity." Has Mr. Motion quite forgotten this letter? 3. On Oct. 22nd, 1901, the medical council wrote another letter to every governor offering to give further details of what they considered to be "the needs of the hospital." 4. In response to these letters a meeting was called and the whole body of governors appointed a special committee of inquiry. On Nov. 14th, 1901, the staff sent to this committee a full and detailed account of the buildings required and of the space they would occupy. 5. A majority of this committee reported on financial grounds adversely to the suggestions of the staff as to the purchase of more land but approved of the proposed buildings, and their report was adopted at a special meeting of the governors who decided that no more land could be purchased considering its great cost. 6 Since that time the medical council have reported on six different plans for buildings and have sent to the Mansion House Committee a full account both of the actions they have taken and the opinions they have expressed to the governors on this matter during the past four years.

And now. Sirs, I will ask any impartial man whether Mr. Motion's letter represents or misrepresents the action of the medical staff? There can be only one answer. But since Mr. Motion has raised this question and now at the eleventh hour advocates the purchase of more land, one may be permitted to ask what action he has himself taken in the past. What steps did he take when he received the circular letter of the staff urging the purchase of additional land more than two years ago? Did he attend the special meetings of governors and strenuously urge that which he now advocates? Did he support the majority or the minority of the special committee? Did he approve or disapprove the decision of the governors to purchase no more land? Did he do anything at all? Was it the medical staff that was supine, or was it Mr. Motion? I shall leave Mr. Motion to answer these questions or not as he likes. In the meantime I will assert that neither Mr. Motion nor anyone else can truthfully say that the staff did not inform every one of the governors most fully of the opinions unanimously held by them and of the action they advised. And it may be further noted that this information was supplied before a yard of Christ's Hospital site had been purchased and before any public appeal had been decided upon. I will not now discuss whether the governors or the Lord Mayor's committee decided rightly or wrongly, wisely or unwisely—that is in many respects a financial matter—but I will say that no single governor can truthfully allege that he was not fully informed of the views of the staff, and no one can now lay the blame on the treasurer, almoners or house committee if he has changed his mind and considers that the governors' decision is now to be regretted Everyone who was a governor in 1901 had his own individual responsibility in the decisions arrived at and amongst these Mr Motion is included

Mr Motion's letter necessarily suggests the question whether it is yet too late to obtain an increased area as well as other questions, but until he has substantiated or withdrawn the statements he has made as to the action of the staff I will not further criticise his position Will he still contend that "the views of the staff have never reached the governors'? He includes in his general charge of "supineness" "old 'Bart.'s' men all over the country, and as he has not specially accused any one of them or myself in particular I will conclude a letter written to vindicate St. Batholomew's men as a whole by signing myself,

Nov 16th 1903 A ST BARTHOLOMEW S MAN

THE ALIEN IMMIGRANT

To the Editors of THE LANCET

SIRS,—I have no desire to enter into a discussion of the very complex question of alien immigration, which I conceive is hardly a question for the columns of THE LANCET But the very partial notice in THE LANCET of Nov 7th (p 1304) of Major W Evans Gordon's book—compiled, as far as the portion dealing with the Jewish population is concerned, as the result of a very hurried scamper through the towns and cities mentioned—prompts a word or two of comment, maybe of protest

In the first place your reviewer's statement that the Jews are "a race apart' and form "a colony permanently distinct" is so far as England is concerned, obviously misleading in the light of a single circumstance The English Jews (i e, those with an English ancestry of not less than one generation), although showing a smaller death rate and larger birth rate than other portions of the community, do not increase in number The explanation of this phenomenon is that while their numbers are kept up by the influx of foreign Jews, their increase is stayed by the fact that there is a steady mergence of Jews in the surrounding population Moreover, does not the assertion that a people who live "permanently apart' from the rest of the inhabitants of the country sound like a prescientific statement? Surely a very little sociological knowledge should be enough to convince anyone that where such a case does occur it is because persecution, or social opinion, by treating the people as a race apart, keeps them in that stage All experience and all study show that once social and legal restrictions are removed the people of any country tend to become homogeneous in their general characteristics Such comments as those are among the most powerful agencies in keeping up the very evil that is deplored I have also to point out that the man who can write of the East of London as a district in the streets of which "it is an exception to hear the English language spoken' possesses knowledge of that part of London which is highly peculiar if not very extensive The East end has, I believe a population of about 1 500 000 On the writer s own showing the foreign population is 88 000 What is the matter with the other 1 412 000? Are they all dumb? Or do the 88 000 talk so much that one cannot hear the other 1,412,000 speak? Is it not a little remarkable that a writer can make such a statement without realising its intrinsic absurdity?

A word on sanitation I have no desire whatever to argue [illegible] in sanita [illegible] what the [illegible] or less, [illegible] London —north, south east, and west And to treat it as a question specially connected with the foreign population is to play directly into the hands of those whose interest it is to obstruct these much needed reforms Moreover, there is one aspect of the Royal Commission s report that ought to have attracted the attention of a writer for THE LANCET The evidence was overwhelming from schoolmasters and others that in the poorer schools the Jewish children were better clothed, better nurtured taller, and mentally more alert than Gentile children And taken with this one may point to the fact that Jews are much more immune than other people during epidemics Looking at these two sets of facts one is driven to the conclusion that either the teaching of science as to the value of sanitation and food is sheer humbug or that the question of our foreign population is but one aspect of the general social question and can only be removed by its solution I prefer the latter alternative

I am, Sirs, yours faithfully,

Stratford E, Nov 10th 1903 MORRIS STREIMER

THE LUNG REFLEX OF ABRAMS

To the Editors of THE LANCET

SIRS—I have read with great interest the letter on the above subject by Dr A. G Auld which appeared in THE LANCET of Oct 17th (p 1118) The subject has occupied a great deal of my attention during the last few months—ever since in fact I read a paper upon it by Dr A Abrams which appeared in *American Medicine* of Jan 3rd last The matter seemed very fascinating and I carefully studied all of Dr Abrams's writings upon it up to date Since then we have tried for these reflexes in a great many patients and healthy people and, on the whole, the results have been disappointing and contradictory Most of our investigations have been made in the Victoria Hospital for Sick Children here and I must thank Dr Graham and Dr Biggar, house physicians in that institution, for their valuable assistance

In order that there may be no misunderstanding I will describe exactly how the tests were made The individual to be examined usually a healthy chested boy, was stripped to the waist and laid in the supine position upon a bed in a quiet, well warmed room The lower borders of the lungs were then very carefully mapped out by light percussion and marked with a dermatograph During quiet respiration these borders were found to alter their position only very slightly Then the individual was requested to take a long breath and at the acme of inspiration the points to which the now distended lungs reached were again marked, most attention being paid to the præcordium and the right vertical nipple line Usually, during forced inspiration, the superficial cardiac dulness almost disappears and the lung descends in the right nipple line from one to two inches Next the surface of the chest was freely sprayed with ether for three minutes or else vigorously rubbed with a coarse towel until it became red Then the borders of the lungs were again carefully percussed out On some occasions a *slight* expansion of the lungs seemed to have occurred the superficial cardiac dulness being encroached upon from above and from the left and the right lung being a little lower in the nipple line and elsewhere, and along with this increased volume an increased resonance occurred But in many cases no such expansion could be detected and in a few the lungs seemed to have actually receded The same uncertainty was apparent in the splenic region These results were so different from those of Dr Abrams that they required repeated confirmation before they could be given publicity I had promised to read a paper on the subject before the Ontario Medical Association last spring but hesitated to do so in the circumstances and hence cancelled the engagement Since then however, we have repeated the experiments many times and always with the same uncertain results Since reading Dr Auld s letter we have most carefully examined 16 individuals using the ether spray, friction, firm plugging of the nostrils with cotton wool, and violent epigastric percussion, and *yet* are not convinced that any considerable or certain expansion of the lung takes place as a result

As already mentioned, in many cases a slight expansion of the lung is detected after the stimulation of the surface over it, while at other times this is not the case During our early experiments we were much struck with this variation in results and hence the following alteration in the technique was introduced and has always been used since The patient is placed on a bed as before and the lung margins are carefully percussed out He is then left for a few minutes and the percussion is repeated. It is thus found that the margins of [illegible] the same positions—sometime [illegible] line and at others within it [illegible] ndent of the respiration and of any stimuli) The resonance of the lung also alters, being greater when the lung is extensive and less when it recedes After repeating this test many times I reported last spring to Professor A B Macallum, our professor of physiology, that the normal lungs seem to be in a state of slow contraction and relaxation, exactly, in fact, as are other organs which contain non-striped muscular tissue. This opinion I feel more than ever confirmed in. In this connexion it should be mentioned that the question of whether or not the bronchial muscles possess tonus is a moot one, Chauveau[1] and Roy and Graham Brown[2] contending that it is normally present, while Dixon and Brodie[3] think that it is only there under certain conditions. We have demonstrated the fact of alteration in the bulk of the lungs repeatedly and in it I believe we have the explanation of the variation in the results obtained during stimulation experiments. The lung normally varying in size, it is hard to say in any given case how much of the expansion is due to the stimulus and how much would have occurred in its absence.

If in a healthy lad the highest and lowest points in the right nipple line be marked between which the border of the lung vacillates during its slow expansion and relaxation it will be found that they are from a quarter to one inch apart. (When the patient takes a full breath the border will descend an inch or more lower still.) This inherent expansion and relaxation are best detected in the upper part of the superficial cardiac dulness and in the right side in the parasternal line. If the chest now be sprayed with ether or vigorously rubbed and the border again be percussed out it will be found that this may or may not have descended, but will probably not have gone below the line which it sometimes reached in its normal rhythmical expansion. In no case will it even approximate to the point which it reaches in forced inspiration. I am aware that this latter statement is quite the opposite of that made by Dr. Abrams who says, "the dislocation of the lung borders by forced inspiration never approaches the dilatation produced by the ether spray,"[4] but I can only state what has been our constant experience.

It is very interesting to note Dr. Auld's quotation from Laennec showing that that most acute of clinicians had observed that the lung possessed an inherent power of contraction and expansion independent of the movements of respiration. One such movement, I believe, is a rhythmical one, depending on the non-striped muscle which the organ contains. This tissue has been shown conclusively to be under the nervous control of the vagus[5] and one would expect *a priori* that it would be effected by reflex stimuli. But the point which I would here make is that stimulation of the surface of the chest does not in our hands produce the constant and extensive dilatation of the lungs which Dr. Abrams has obtained. To give another concrete case. Dr. Abrams states[6] : "If the ether spray is directed on the borders of the lungs posteriorly the lung borders will descend from two to four inches, dependent upon certain conditions." To-day I examined two boys, aged 12 and nine years, both suffering from cataract but otherwise healthy. In each I carefully percussed out the lungs posteriorly, they being in the sitting posture I then sprayed the older boy with ether over the right base for three minutes and rubbed the younger one with a rough towel until he was red. In neither boy could the lung be found to have descended at all. Yet Dr. Abrams says that the lung reflex as an aid to diagnosis is specially useful in pediatrics.[7]

Dr. Abrams believes that the degree of activity in which the reflex is present is an indication of the condition of the lung, it being less marked than normal, or absent, in cases of early tuberculosis. But in our experience the phenomenon is altogether too uncertain to have any clinical significance in this respect. I will not follow Dr. Abrams and Dr. Auld into the fascinating field of the application of the "lung reflex of dilatation" to the explanation of certain diseased conditions, such as asthma and emphysema. Dr. Auld accepts as fact Dr. Abrams's belief that hot poultices applied to a child's chest relieve pulmonary collapse by causing a long-continued reflex dilatation of the lung. To accept this would be to assume that pulmonary collapse in broncho-pneumonia is due to a continued spasm of the non-striped muscle of the lung tissue, and I think that such a view would not appeal to pathologists. Because a hot poultice gives relief to a child suffering from broncho-pneumonia it does not at all follow that it acts by producing a "reflex of dilatation." There are other theories that are just as likely.

Dr. Auld quotes Dr. Abrams extensively in regard to many other points in connexion with reflex dilatation and contraction of the lung. But before the medical profession accepts as proved that plugging of the nostrils with cotton-wool or strong percussion in the epigastric region causes marked dilatation of the lung or that percussion over the manubrium sterni produces reflex contraction of the same, these phenomena must be much more extensively tested by different observers than has been done up to the present. We have not investigated these points so fully as we have the matter of lung dilatation from stimuli applied to the thoracic surface, but the few experiments that we have made have been distinctly negative. I can certainly say this much : 1. It is possible to plug firmly both nostrils of a healthy individual without producing any appreciable dilatation of the lungs. It seems, however, to stimulate respiration. 2. It is possible to percuss forcibly the epigastrium with an equally negative result.

Dr. Abrams has done good service in drawing attention to these matters. His work has been of a pioneer nature and, like most pioneer work, will not be final. It is to be hoped, now that Dr. Auld has drawn the attention of the English profession to the subject, that it will receive the full investigation that it deserves and that thus the extent and significance of the lung reflex will take their true position in the field of medicine. I have used the term "rhythmical contraction and dilatation" on several occasions, meaning an alternate contraction and dilatation. Whether such alterations occur at regular intervals of time we cannot say at present.

I am, Sirs, yours faithfully,

Toronto, Canada, Oct. 30th, 1903. ROBERT D. RUDOLF.

To the Editors of THE LANCET.

SIRS,—In a further communication of much interest Dr. Harry Campbell defends his thesis as to thoracic expansion in a series of arguments characterised by great ingenuity. It would not be so easy perhaps to establish the existence of the lung reflex of dilatation were theoretical considerations alone to weigh, but I fear that the positive evidence obtainable is such as to rebut even the relentless logic of Dr. Campbell, as I shall presently point out.

First, however, with regard to Dr. Campbell's complaint that I unwittingly failed to do him justice in respect of his view as to the causation of thoracic expansion, I must firmly, though courteously, resist it. I made it perfectly clear, as I trust, that experiments had shown that there was "a certain point to which the chest may expand beyond an ordinary inspiration which does not necessitate any action on the part of the inspiratory muscles as the inhibition of the lung pull is of itself sufficient to produce it" and then I go on to say that when Dr. Campbell "makes the general assertion that 'any enlargement of the chest ...... is chiefly brought about by the inspiratory muscles' he fails to appreciate that enlargement (up to a certain point) which is brought about by the reserve recoil of the chest wall." Now, in making use of the words "*any* enlargement" Dr. Campbell includes such enlargement as may be brought about solely by pulmonary relaxation—i.e., apart altogether from the inspiratory muscles. I have never denied that Dr. Campbell takes pulmonary relaxation into account; what I took him to task for (to quote his own expression) was not for disregarding this factor but for asserting that this factor is not alone able to produce a certain degree of thoracic expansion, without, that is, any aid on the part of the muscles of inspiration. Holding tenaciously as he does to the view that any degree of thoracic expansion is chiefly brought about by the muscles of inspiration it is perfectly evident that it would be impossible to convince Dr. Campbell that even a local lung reflex may be quite independent of such muscular action, but while Dr. Campbell is merely supporting a theory the evidence as to a purely passive recoil of the chest is founded on well-authenticated experiments.

There is a good deal of debatable matter in the subsequent theoretical observations of Dr. Campbell in respect to the functions normally exercised by the inspiratory muscles as, for instance, that the initial "stretching" of the infant's lung tends to be kept up permanently. It is true that after birth the lungs must expand and that the child's inspiratory muscles undergo a shortening or, in other words, acquire their normal tonus, but this once established and regulated to the newly acquired pulmonary elasticity it by no means follows that such action is thereafter maintained and perpetuated to a similar purpose, as the conditions are not parallel. The conditions are, in fact, reversed and the inspiratory muscles instead of endeavouring to establish a pulmonary suction are in reality directed rather against it. With regard to the function of the pulmonary suction in facilitating cardiac diastole this is surely a well-established fact in pneumono-dynamics.

[6] Medical Record, April 22nd, 1899, p. 562.
[7] New York Medical Journal, Jan. 13th, 1900.

Coming, however, to the point chiefly at issue—viz., a lung reflex of dilatation—it was pointed out in my last letter that when this reflex is induced the expansion of the chest is more persistent than that produced by voluntary deep breathing, but it is to be observed, as has been pointed out by Abrams, that in the case of the lung borders these can also be made to *descend* to a much greater extent than is possible by forcible inspirations. Nor can we assume that herein "some degree of dyspnœa is produced" which can possibly account for the phenomenon. Both careful percussion and the fluoroscope demonstrate that the downward extension of the lungs which can be produced reflexly may exceed by quite two inches that produced by inspirations. The fluoroscopic picture shows a greater general increase of brightness in the former case, specially well marked in the complemental spaces, lasting from two to three minutes. An increase of brightness is also produced whatever area of lung is stimulated and even over quite small areas. That cutaneous stimulation, whether in the form of ether spray, or cold, or rubbing, or the electric brush, excites the respiratory centre is true, but if such action were so limited the ensuing lung dilatation would be measured by that due to inspiratory effort, whereas we have, in fact, a lung dilatation which much exceeds this.

Dr. Campbell is right in his reference to the bronchial dilatation following the absorption of drugs into the blood, but the word reflex was really an oversight, as all I meant to convey was the fact of bronchial dilatation apart from the primary induction of respiratory effort chiefly in connexion with the experimental work previously referred to. In conclusion I beg to thank Dr. Campbell for his able and kindly criticism respecting work for which I myself do not claim a particle of credit. It has been merely my endeavour in the light of what little experience I possess to attempt a vindication of the character of the work which has been most carefully conducted by our *confrère* on the other side of the Atlantic. And let me also thank you, Sirs, in so generously affording room for the discussion of the subject.

I am, Sirs, yours faithfully,

Henrietta-street, W., Nov. 7th, 1903. A. G. AULD.

THE PREVENTION OF THE RECURRENCE OF NASAL POLYPI.

To the Editors of THE LANCET.

SIRS,—In an interesting article under the above heading which appeared in THE LANCET of Nov. 7th, p. 1295, Dr. E. S. Yonge states that "Lambert Lack has comparatively recently made some valuable observations on the origin and the radical treatment of polypi." While fully recognising the admirable work of Dr. Lambert Lack in this branch of surgery the discovery of the origin and the credit for the radical treatment of nasal polypi are undoubtedly due to my father, Dr. Edward Woakes, who published his observations on this subject in 1885, and by whom the radical operation has been performed for over 20 years. A reference to my father's book, "Nasal Polypus, with Neuralgia, Hay Fever, and Asthma in relation to Ethmoiditis," will show that thorough investigation of the subject had been carried out by him before the year 1882, and, moreover, that the reports of the pathologists Thurston and Martin, which Dr. Yonge states practically confirm Dr. Lambert Lack's observations, were, in fact, reports made by these gentlemen at my father's request from specimens of the disease provided by him, and the reports were subsequently published by him.

In cases of multiple polypi I have performed the radical operation referred to by Dr. Yonge for upwards of eight years in private practice as well as at both the London Hospital and the London Throat Hospital. In these cases I follow my father's method by operating with the patient in a sitting posture. This is most important, as it is essential throughout the operation to have a clear view of the locality under treatment; also in the course of the operation frequent digital examinations should be made. After removing with forceps the large polypi and middle turbinate I use a heavier and [illegible] the removal of the [illegible] ration to which Dr. [illegible] the operator has a [illegible] the relations of the parts in the region of the operation and uses antiseptic precautions throughout, and if the patient be thoroughly anæsthetised by a competent anæsthetist.

I am, Sirs, yours faithfully,
CLAUD E. WOAKES,
Surgeon to the London Throat Hospital.
Harley-street, W., Nov. 12th, 1903.

A GROUP OF CANCER CASES.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the article in THE LANCET of Nov. 14th (p. 1356) on "A Group of Cancer Cases." As I am a believer in the infectivity of cancer possibly a few more cases may be of interest to your readers.

In 1901 I attended an old gentleman with cancer of the larynx from which he died; he was a smoker, but nearly blind, so his valet used to light his pipe for him and in doing so used to take a few "draws." The valet has just died in St. Thomas's Hospital from cancer of the pylorus. In this neighbourhood are several "cancer houses." In one house five persons have died from cancer. I attended the latest one after Sir Frederick Treves had operated on him and he (Sir F. Treves) told me that he knew a row of cottages every one of which was a "cancer house." In another house here 15 years ago I attended a woman who died from cancer of the rectum; the next woman who occupied the house died two years ago from cancer of the vagina and vulva. Just across a lane another woman died from cancer of the uterus. In another house a man I attended died from cancer of the rectum; the house was empty for about two years, then a lady took the house and four years afterwards had the breast removed for cancer, from which she ultimately died. The diagnosis, curiously enough, has in every case been verified by a London surgeon.

If the disease be not infectious or endemic all these and similar cases on record must strain "coincidence" to breaking point. I am at present searching for "histories" of certain houses in a district and believe I shall have still more cases to record.

I am, Sirs, yours faithfully,
A. CHARPENTIER, M.D.Durh., D.P.H.R.C.P S Lond.
Uxbridge, Nov. 16th, 1903.

THE TREATMENT OF GOITRE BY THE USE OF DISTILLED OR RAIN WATER.

To the Editors of THE LANCET.

SIRS,—With reference to Dr. A. E. Taylor's letter on this subject in THE LANCET of Nov. 7th (p. 1324) I should like to point out that his first two cases seem to be cases of exophthalmic goitre, which surely claim a different etiology to those of endemic goitre and the treatment of the former disease by the use of rain or distilled water is not in question. Case 4 is one of endemic goitre of long standing and these cases, as a rule, do not benefit to any extent from this treatment in my experience at least. So much depends on the amount of gland tissue remaining; the more the fibrous element in the goitre the less hope of ameliorating. Case 3 theoretically should have derived benefit, but I notice that the water-supply of the district is stored in galvanised iron tanks. Some salt of iron (if not a bacillus) is, in my opinion, the cause of endemic goitre and one would like to know from Dr. Taylor as to the presence or absence of iron in the water-supply of Outtrim, especially if the water remains for some time in the tanks.

I may say I have had several cases in this district where a goitrous mother has given birth to a goitrous child.

I am, Sirs, yours faithfully,
LOUIS E. STEVENSON, M.B., B.C. Cantab., F.G.S.
Temple Sowerby, Penrith, Nov. 10th, 1903.

THE RELATIVE EFFICIENCY OF RADIUM SALTS.

To the Editors of THE LANCET.

SIRS,—I should like to direct attention to a practical point connected with the medical use of tubes of radium compounds. Two tubes in my possession, each invoiced as containing five milligrammes of pure radium bromide, exhibit the following differences:—

—	Old radium bromide tube.	New radium bromide tube.
Action on acidified (HCl) common salt in two hours.	Turns it buff colour.	Produces no apparent change.
Relative effect on barium platino-cyanide.	4	1
Colour of radium compound.	Brownish yellow.	Pale yellow.
Colour of the glass of the tube.	Dark violet.	Palest violet.

It is manifest that in acting on organic tissue the old tube would be far and away the more effective and that as a preliminary to progress some simple test of efficiency is wanted, such as the first one I have given. While the differences noted here may possibly be owing in part to trade qualities it is not improbable that age is the chief cause, the gradual change of colour of radium salts being concurrent with increased effectiveness.

While addressing you may I also turn the attention of investigators to another part of the subject? It is now recognised that the efficacy of x rays and Becquerel rays is due to their pulsating character. *A pulsating character* can be conferred on ordinary light by mechanical means, as in Bell's device for the production of sound by radiant energy, which will be found described in *Nature*, vol. xxiv., pp. 42-44, 1881. The action of such a mechanically produced intermittent beam of coloured light has not, so far as I am aware, been tried on bacteria. If it should prove to be bactericidal its analogy to the afore-mentioned rays would be established and there would be the possibility of its use as one of the cheapest therapeutic agents of its kind.

I am, Sirs, yours faithfully,
WILLIAM ACKROYD, F.I.C., &c.,
Public Analyst for Halifax.
Halifax, Yorks, Nov. 16th, 1903.

THE RELATION OF THE ANÆSTHETIST TO THE PATIENT AND TO THE SURGEON.

To the Editors of THE LANCET.

SIRS,—It is hardly open to question that the position of the anæsthetist whose duty it is to take the life of his patient in his hands while the surgeon performs an operation has never been at all clearly defined. Surgery has had its prophets from time immemorial while anæsthesia has but recently celebrated its first 50 years of practical existence. Almost from the day that Morton used ether and Simpson introduced chloroform there have been medical men who, by reason of their special researches or practical experience, have become expert anæsthetists. Our hospitals have found it necessary to add to their staffs members whose duty it is to undertake the sole responsibility of the anæsthesia, and by the recent decision of the English Royal Colleges and of the University of London these gentlemen now assist in furthering the work of the hospital medical school by teaching students to acquire practical skill in anæsthetics. However, the grave responsibility which these duties have imposed upon these specialists—for specialists they are compelled to be if their attendance at their hospitals and their teaching are taken at all *seriously*—and the necessity for devoting their whole [illegible] and energies to their one branch of medicine have never [illegible] the recognition that might have been expected. No [illegible] reason far to seek. The subject of anæsthesia has [illegible] been studied, or, indeed, understood, in its entirety by [illegible] majority even of the profession and until of late years [illegible] but few of the public. This has led in many instances to a belittling of the importance of the anæsthetic and still more so of the responsibility incurred by the anæsthetist. No one willingly commits his life to the inexpert chauffeur or shoots in covert with a novice, but when the question of taking an anæsthetic is broached the average individual evinces little interest in the matter and is content to leave his life to the tender mercies of anyone who adopts the rôle of anæsthetist. When fatalities arise it is assumed that such deplorable occurrences are inevitable and prevision can hardly obviate them. It is cheerfully surmised since the mortality is low that with luck the individual will escape and that whether he does so or not is rather a matter of chance than the natural result of skill or inexperience.

The relation subsisting between the hospital surgeon and his colleague the hospital anæsthetist is usually cordial and one of mutual respect. It is, however, at present unfortunately the case that the anæsthetist has few opportunities of gaining a knowledge of his patients. Except an often perfunctory examination of the chest immediately before the administration of the anæsthetic there is no chance given to the anæsthetist of studying the case. In some instances this must prove detrimental to the patient. When the anæsthetist undertakes work *sine honorario*, and he does so with wholehearted willingness, it is usually at the request of his surgical colleague and without the personal request of the patient's friends and often without any subsequent expression of their gratitude. This state of affairs, which is not, perhaps, of any personal importance to individual anæsthetists, reacts upon them as a class and tends to retard the progress of the study to which they have committed themselves. It is assuredly injurious that the personal or "patient" element should drop out of any branch of the healing art. When it does so there is always the fear that the financial side will attain undue proportion while the worker loses to some extent his pride in his branch of practice, and his zeal for improvement and advance grows cold if it does not die out altogether. The remedy seems to be that as the old conditions have passed away and the anæsthetist is no longer a house surgeon or a dresser there should be a closer relationship cultivated through the medium of the surgeon between the anæsthetist and his patient, that when possible arrangements should be made directly between them, or at all events after consultation with the anæsthetist. That this is becoming more the custom in the better class of practice may be conceded, but the contention of the writer is that such conventions should be generally recognised and be the rule instead of the exception as at present.

I am, Sirs, yours faithfully,
ANÆSTHETIST.
Nov. 17th, 1903.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Neglect of Sanitation in Mofussil Towns.—The Plague Epidemic.

IN the Government resolution on the reports concerning the municipalities of Bengal attention is drawn to the fact that the supervision of the municipal commissioners over their waterworks is of little practical value and that neglect of the machinery and filters and abnormal waste of coal are faults that are constantly brought to the notice of the Government. That these things should continue year after year suggests that these municipalities should be made to feel a higher power and that the officers concerned with the neglect of such important works should be reminded of their duty. I note, however, that inspections of these works are not made annually and the Lieutenant-Governor appears to lament the want of means of comparison between the several installations. Some of the problems dealing with conservancy seem to be as far off solution as they were 20 years ago. Among them may be mentioned the following: Should the sewage be removed directly by carts or from depôts? Should a light tramway be used? What is the best form of cart? How is the cart to be got beyond the edge of the trenching ground in the rainy season? Can all the waste fluid from the houses be removed by carts and, if not, how is that which must be removed to be separated? What suitable private latrine can poor ratepayers afford? How are the upper storey privies to be dealt with? A report on the work of the local boards of Assam has appeared from which I extract the curious information that while over a lakh of rupees was spent on dispensaries and more money still on education only Rs 8228 (under £600) were spent in sanitation This amount was directed chiefly to improvements of water supply by the construction of new tanks and wells and in the clearance and repair of old tanks The absurdly small amount is another illustration of the general neglect of sanitation, as this is for a whole province and not merely for one or two towns Cawnpore city, with a population of 180 000 is at last to be provided with an underground system of drainage The main sewer is completed and runs for nearly seven miles from one end of the native city, through the cantonment, to the river Ganges, but the subsidiary sewers are now being constructed Unfortunately it is reported that plague has again developed in this city and is rapidly assuming alarming proportions

The mortality from plague throughout India has again made a halt in its otherwise rapid rise of the past few weeks The last figures show 16 300 deaths for the week, distributed over India as follows —Central Provinces, 1401 , Hyderabad State, 1145 , Mysore State 761 , Madras Presidency, 231 , United Provinces, 156 , Bengal, 123 , Bombay city, 64 , Rajputana, 59 , Bombay Presidency, 10 386 , Central India, 1585 , Punjab, 353 , Calcutta, 17 , and Karachi, 3

Oct 30th

THE UNIVERSITY OF TORONTO OPENING OF THE NEW MEDICAL SCHOOL AND LABORATORIES

(FROM A SPECIAL CORRESPONDENT)

THE ceremonies in connexion with the opening of the new medical school and laboratories of the University of Toronto marked an episode of considerable importance Although the occasion was the opening of the building it was also, in a measure the celebration of the amalgamation of the two great medical faculties of the Province of Ontario—viz , that of Trinity College, Toronto (also a University with the usual faculties), and that of the University of Toronto The ceremonies were initiated with a luncheon given by the Dean Dr Reeve, to his colleagues and a number of distinguished guests on Oct 1st in the east examination hall The toast of "His Majesty the King" having been duly honoured Dr Reeve gave the toast of "The Lieutenant Governor," the Visitor of the University The Lieutenant-Governor, Mr Mortimer Clarke who has warmly supported the University for more than 40 years and who has taken an active interest in the medical faculty from its inception, having responded, the chairman next proposed the health of Professor Goldwin Smith whom he described as the Nestor of university graduates present In his reply Professor Smith referred to the approaching realisation of university federation in Ontario, as evidenced by the union of the medical faculties of Toronto and Trinity, and eulogised the medical profession of which his father had been a member, for the services it had rendered to mankind

At the conclusion of the luncheon the company adjourned to the north lecture theatre of the new building where Mr John Hoskin, LL D , on behalf of the board of trustees presented the keys of the building to Dr Loudon the President of the University Dr Hoskin congratulated the University upon the fact that in spite of a disordered labour market and troublous time in the financial world the new building had been erected and furnished in 14 months He referred warmly to the interest taken by the Government in the progress of the University as evidenced by promises of future grants

Dr LOUDON, after accepting the keys and presenting the thanks of the University to the board of trustees, gave in outline the history of medical education in Toronto

The PRESIDENT then introduced Professor C S SHERRINGTON who delivered the inaugural address on Medicine and Science in the Modern University, which was published in THE LANCET of Nov 7th, p 1273

Addresses were then delivered by the following gentlemen who brought messages of congratulation from their respective universities Professor WELCH, of Johns Hopkins University , Professor CHITTENDEN, of Yale University , Professor TOWNSEND PORTER, of Harvard University ; Professor RODDICK, Dean of the Medical Faculty of McGill University ; Professor A C ABBOTT, of the University of Pennsylvania , Professor J P MCMURRICH, of the University of Michigan (a graduate of Toronto) , Professor BARKER, of Chicago University (also a graduate of Toronto) , and Professor ROSWELL PARK, of the University of Buffalo

In the evening Professor W OSLER delivered an address to the students entitled "The Master Word in Medicine" which was full of pleasant reminiscences of his own student days at the University of Toronto

Dr REEVE followed speaking with great energy in spite of being partially disabled by an attack of influenza He said that it was in accordance with the fitness of things that the medical faculty of the University, as the senior faculty, should put away childish things and set an example of sensible conduct to the undergraduate body and he congratulated his hearers upon [illegible] the ceremony He pointed [illegible] opening of a building for [illegible] its details, for the first time in the province They had the first example given to the world of the unit system of laboratory construction devised by Dr Minot of Harvard They were also incidentally celebrating the union of two medical faculties which had been working side by side for years in honourable rivalry but in hindrance of the full development of each He particularly referred to the expense and difficulty of maintaining even one complete system of laboratories for medical instruction and to the foolish waste which resulted in any attempt to duplicate such instruction In his concluding remarks he expressed the hope that the students would ponder over the words which had fallen from Professor Osler and that they would remember that they had been listening to one who was once an undergraduate like themselves in the University of Toronto but who by virtue of the talisman "work" was to day the medical author *most widely read in Great Britain* and the most distinguished clinician in the United States

An address from Dr J A TEMPLE of Trinity College terminated the proceedings of the day

On Oct 2nd addresses were delivered in the north lecture theatre by several of the visiting professors, including Professor W W KEEN Jefferson Medical College, Philadelphia, Professor WELCH, Professor J G ADAMI of McGill University, and Professor ABBOTT In the south lecture room addresses were delivered by Professor CHITTENDEN, Professor SHERRINGTON, Professor BARKER, and Professor PORTER, the last of whom pointed out that it was not what one knew from the point of view of theory that was all important but the knowledge of the manner in which the facts and generalisations of physiology were obtained Visits were then made to the new laboratories and lecture rooms of the affiliated Royal College of Dental Surgeons under the guidance of the dean of the department, after which the President of the Union of [illegible]

At a special convocati[illegible] already announced in TH[illegible] received the degree of LL D *honoris causâ* from the hands of the Vice Chancellor, the Hon Charles Moss, Chief Justice of Ontario , Professor Keen, Professor Welch, Professor Osler, Professor Chittenden, Professor Sherrington, and *in absentia* Professor Bowditch

The ceremonies came to a conclusion with a dinner given by the Faculty of Medicine to over 100 guests the speakers including the Hon Richard Harcourt Minister of Education , Professor Irving H Cameron Professor Osler, Professor Keen, Professor Sherrington Professor Welch Mr Byron E Walker, Dr James H Richardson and Mr Alfred Mosley, C M G , who we need hardly remind our readers equipped and maintained an ambulance and nursing staff in South Africa during the war and who subsequently sent out a labour commission to the United States and is now supporting an educational commission to the same country

POST-GRADUATE WORK ABROAD

(BY A SPECIAL CORRESPONDENT)

V FLORENCE [1]

A SERIES of what are known as private courses in various subjects is given yearly in connexion with the Royal Institute for Superior Studies of Florence These courses, which are only open to graduates, commenced this year on Nov. 16th and will end on Dec. 12th, one lecture in each course being delivered three times a week, and are conducted by some of the best known Florentine professors such as Lustig, Grocco, Mya, and Pestalozza. To be admitted to a course the graduate is required to make written application to the president of the faculty on stamped paper and to present his diploma and the receipt for the fees (20 lire for each course with an additional laboratory fee of five lire for practical classes). Foreign graduates may attend but no undergraduates are admitted. The following list of the courses with the names of the professors who are to conduct them will show the range of post-graduate study at Florence :—

---

[1] No I (Paris) No II (Berlin) No III (Vienna), and No IV. (Budapest) were published in THE LANCET of Sept 12th (p 781), Sept. 26th (p. 912), Oct 17th (p 1121) and Oct 24th (p 1194) 1903, respectively

Demonstrations on topographical anatomy with its applications in practice.—(Professor Giulio Chiarugi.)

Practical questions in vaccination and serum therapeutics.—(Professor Alessandro Lustig.)

Physiology.—Demonstrations of the blood and lymph and of the circulatory and lymphatic systems, with special reference to technical methods applicable in medical practice (Professor Giulio Fano).

Hygiene in reference to environment, epidemiology, and buildings.—(Professor Giorgio Roster.)

Legal medicine.—Human blood stains and the biological theory of reacting serums; micro-chemical technique in the emergencies of medical practice; Gosio's method of vaporisation of arsenic; accidents to workmen and questions relative thereto affecting the rights and duties of medical practitioners (Professor Angelo Filippi).

The new remedies studied experimentally in reference to their pharmacology and therapeutics.—(Professor Giovanni Bufalini.)

Clinical medicine.—Demonstrations of the most important cases in the Medical Clinic, with special reference to the most recent observations regarding the diseases which they illustrate (Professor Pietro Grocco).

Clinical surgery.—Similar demonstrations of cases from the Surgical Clinic with the same object (Professor Enrico Burci).

Physiology and pathology of alimentation.—Demonstrations on cases from the Dispensary and the Clinic of Pædiatry (Professor Giuseppe Mya).

Psychiatry.—Demonstrations on cases at the Lunatic Asylum (Professor Eugenio Tanzi).

Diseases of the eye, with special regard to the needs of medical practice; separate classes for the study of ocular symptoms in nervous and constitutional diseases (Professor Luigi Guaita).

Practical course of gynæcological therapeutics in dispensary practice.—(Professor Ernesto Pestalozza.)

Dermosyphilopathy.—(Professor Celso Pellizzari.)

Operative medicine, with special regard to the operations most urgent and most frequent in medical practice (Professor Giovanni del Greco).

Physical diagnosis.—Practical illustrations of the principal methods of physical examination of the circulatory, respiratory, and digestive systems (Professor Umberto Flora).

Diseases of the nose, the throat, and the ear, with special reference to the requirements of medical practice.

Chemistry, microscopy, and bacteriology applied to clinical work.—(Professor Giuliano Daddi.)

Some important modern methods of clinical diagnosis, with special reference to recent methods such as the investigation of agglutinating power, the examination of cerebro-spinal fluid obtained by the syringe by lumbar puncture (Professor Cesare Baduel).

The lectures are all in Italian, a certain knowledge of which language is therefore essential to the student desiring to attend any of them. The ordinary medical classes of the Florence School (which, by the way, is not one of the Italian universities) are also open to foreign graduates, or indeed, to any student who may care to attend them, on payment of the fee. By frequenting these anyone may study under teachers so well known in their special departments as Professor Grocco, Professor Lustig, and Professor Banti. No private clinics in Florence, so far as I am aware, are open to foreign medical men unless perhaps by personal favour.

VI. MILAN.

Arrangements are at present being made for the institution of post-graduate courses in Milan. The prime mover in the undertaking, Professor Mangiagalli, has already succeeded in bringing into line the Commune, the Province, and the Ospedale Maggiore of Milan, by means of which all facilities will be afforded to students and teachers to profit by the large amount of material for clinical study available in that populous centre, and he is now endeavouring to obtain Government support for his scheme. Already the Minister of Public Instruction, Signor Nasi, has promised to ask the Government to sanction the grant of a subsidy of 20,000 lire (£800) towards the foundation of the new polyclinic and so soon as the expected coöperation of the Government is secured no time will be lost in putting the scheme into execution. For the present the idea is to start with three clinics—namely, (1) an obstetrical and gynæcological clinic in connexion with a hospital of 200 beds; (2) a clinic for diseases incidental to various occupations (*malattie professionali*), with material for study derived from 60 beds; and (3) a clinic for epidemic and contagious diseases, with a hospital attached for contagious diseases consisting of seven pavilions with 164 beds. The foundation of this polyclinic is regarded as a great boon in prospect for the younger medical men, especially those in the northern part of the kingdom, and it will probably also attract a good many foreign graduates on account of the large amount of material upon which the institution will be able to draw for teaching purposes in such a city as Milan.

BIRMINGHAM.

(From our own Correspondent.)

Foundation of a Huxley Lectureship in the University.

At the last meeting of the council of the University a letter was read from Professor Poynting, F.R.S., stating that he was commissioned by a friend, who desired to remain anonymous, to offer to the University a sum of money capable of producing annually £20 for the endowment of a lectureship, in the University to be called the Huxley Lectureship. The intention is that the lectureship shall not only keep in memory the work and life of an eminent man of science but also his connexion with Mason College, the forerunner of the University, for at the opening of that institution an address was delivered by Professor Huxley. The donor of the endowment has only specified that a lecture shall be given annually, either in the winter or spring terms, and that it shall be open to all members of the University without any payment. The council of the University has accepted the gift and, in accordance with the wish of the donor that some person who had been a friend of the late Professor Huxley should be the first lecturer, has, on the advice of the senate, agreed to invite Sir Michael Foster, K.C.B., F.R.S., to deliver the first Huxley lecture.

Hospital Saturday Fund.

The meeting at which the cheques for the year are distributed to the representatives of the institutions benefited by the Fund has recently taken place. As mentioned in a former letter the sums of money allotted to the hospitals are exactly the same as last year and amount in all to £10,000. The Lord Mayor presided on the occasion of this meeting and Alderman Cook, the chairman of the Fund, was present and stated that he hoped that it would be a very long time before a less sum than £10,000 was voted to the hospitals by his committee. He was glad that there was an appreciable improvement this year, for 76 more contributions and £607 more were received on the actual Hospital Saturday than was the case 12 months ago. The Lord Mayor, in his speech, congratulated the committee on again establishing a record, since the contributions for this year amounted to £18,553 as compared with £18,036 obtained in the previous year. It was undoubtedly the weekly system that added so much to the large revenue which they were able to obtain He had pleaded before to manufacturers to allow their establishments to participate in this work and it was very gratifying to know that this year the number of firms showed an increase of 101. There were, however, still 400 or 500 firms in the city who did not subscribe and he appealed to them to coöperate. In conclusion, he pointed out that since the establishment of the Fund the hospitals had received altogether £222,337, the General Hospital having received £70,710, the Queen's Hospital £43,155, the Dispensary £23,861, the Children's Hospital £18,332, and the Eye Hospital £15,000.

Bequests to Medical Charities.

On Nov. 13th was buried Miss E. J. T. James, a lady who had individually and in union with her sister, who died a few years ago, devoted a large amount of her money to charitable objects, including almshouses, pensions for poor gentlewomen, &c By the terms of her will a number of hospitals receive handsome legacies, free of duty The following come in for £1000 each the General and Queen's Hospitals Birmingham, the Eye Hospital and the Blind and Deaf and Dumb Asylums in the same city, the Hospital for Incurables at Putney, the Cancer Hospital, London, and the Hospital for Consumption, London A legacy of £500 is left to the Hospital for Incurables at Leamington

Birmingham and District General Medical Practitioners' Union

Regret is expressed by the *Midland Medical Journal*, the organ of the above union, that the Walsall Medical Society has decided to withdraw from the position which it has held up to now of being a ward of the union It is pointed out that the society will be weaker by itself than in combination with the other wards of the union and that the multiplicity of small societies is a great hindrance to a complete organisation of the profession It is stated that the reason for this decision on the part of the Walsall Medical Society is that their town had received no help whatever from the union when it attempted to stop the penny a week clubs On the other hand, it is pointed out by the journal on behalf of the union that the attendance of the Walsall delegates at the council meetings was most irregular, one having put in no appearance for a year and the other only having attended two out of ten meetings, so that the views of the Walsall Society were not properly made known to the other members Moreover, it is pointed out that when the union issued a recommendation to neighbouring general practitioners to refuse to have anything to do with touting clubs out of 34 practitioners in Walsall at that time only six consented to fall into line If the information of the editor of the *Midland Medical Journal* is correct it would appear as if, as he puts it, Walsall were in a parlous state unless matters have mended since the issue of the circular to which attention is called

Health of the City

The report on the health of the city for the third quarter of the year shows that though the birth rate was very low (32 2 per 1000) the death rate (15 6 per 1000) was also unusually low, indeed only once before—viz, in 1894 when it fell to 14 8 per 1000—has so low a death rate been recorded for this particular quarter This is chiefly due to the small amount of mortality from diarrhœa Most of the infectious diseases were less prevalent than usual, the typhoid fever cases in particular being much below the average number Unfortunately the cases of diphtheria show an increase The outbreak of small pox, though not extensive, has caused the authorities much anxiety This is the last report which will appear under the name of Dr Alfred Hill, for he vacated his position on Sept 30th, when Dr J Robertson, the newly appointed medical officer of health, took up the duties of office

Sanatorium for Consumptives in Staffordshire

A conference presided over by Lord Hatherton, chairman of the Staffordshire county council, has recently been held to consider a proposal to establish a county sanatorium for tuberculous patients A site just outside Lichfield has been offered by Colonel Wilkinson who has given the inhabitants of that city, should they view the establishment of such an institution in their vicinity with apprehension, the alternative of purchasing the piece of land for the sum of £2400 such sum to be applied to the purchase of another plot of ground in some other part of the county Lord Lichfield said that the county medical officer had drawn up a report from which it appeared that the death roll in Staffordshire from phthisis was 800 per annum and that there were at least 2000 sufferers in the county It also expressed the opinion that the open air treatment was both curative and preventive The report recommended the establishment of a central hospital for the accommodation of 50 patients The cost of erection of the sanatorium was estimated to be £17,500 and the maintenance something like £5000, of which the county council would find £2500 leaving the other half to be provided by the local authorities It had been suggested that chalets should be erected instead of a sanatorium but in a climate like that of England such places would be unsuitable The Mayor of Smethwick moved—

> That this meeting is of opinion that it is desirable to provide a sanatorium for cases of pulmonary tuberculosis in the county, and
>
> any specific proposals the
> ent would gladly welcome
> any scheme having that
> ay submit for the approval
> set forth in the report of

In the course of the discussion upon this motion Mr T Bamford of Uttoxeter said that in his opinion a saving could be effected by sending patients to existing institutions at the seaside—a saving in the case of first class patients of 2*s* 6*d* per week and of second class patients of 12*s* 6*d* per week He contended that the climate of Staffordshire rendered it unsuitable for the treatment of these cases during the winter months He also suggested that phthisis should be made a notifiable disease, pointing out that its cause was insanitary surroundings coupled with an overworked and underfed population The Mayor of Lichfield said that the city council had passed a resolution in favour of the sanatorium being erected on the site given by Colonel Wilkinson near their city After a lengthy discussion, to which Dr G Reid the county medical officer of health replied, the motion was carried

Nov 14th

MANCHESTER.

(FROM OUR OWN CORRESPONDENT)

Anthrax in Cheshire

FOR some months past anxiety has been felt on account of the existence of anthrax in Lancashire and Cheshire In any case the danger of its spreading and of its communication to man is considerable but it is increased by the fact that among the farmers some are to be found who, either from want of intelligence and education or from heedless selfishness, disregard all warnings and try to sell animals which are suspiciously ill It is done without regard to the terrible consequences that may follow As mentioned a fortnight ago, two men were summoned at the Eddisbury petty sessions for not notifying cases of anthrax At the meeting of the Cheshire county council on Nov 12th it was stated that there were four outbreaks during the last quarter in none of which the existence or suspected existence of anthrax was reported Nothing would probably have been heard of them if the carcasses of the animals had not been sent to the Manchester abattoirs and examined by the chief inspector who brought the matter to the notice of the chief constable of Cheshire Six persons are stated to have been attacked with anthrax as the result of these outbreaks Professor S Delépine was supplied with organs from the animals in the four cases referred to and he sent a very important report to the county council in which he said that for the last few years he had had to report on cases of anthrax occurring in man and animals in Cheshire Lancashire, and Derbyshire and that his impression was that it was much more prevalent in these counties than was generally supposed Beyond the immediate danger connected with a given outbreak there is the further most serious consequence that the field which has been occupied by the diseased cattle will be liable to permanent infection "Each beast slaughtered in a cow shed or field was liable to cause permanent infection of the spot where anthrax blood was spilt,' so that a few undetected cases might ' be followed by a gradual generalisation of the disease in districts naturally damp " Without disinfection such land is fatal to stock and, unfortunately, it is a difficult and costly proceeding to get rid of the bacillus anthracis As Professor Delépine says, the land should not be used as a pasture but peas and beans would be safe crops to grow He adds further that it would be more advantageous 1 That the field should be well drained 2 That a heavy top dressing of lime would be beneficial, after which some say it would be safe in the course of a few months but this he doubts But if the field is not very extensive he would feel inclined to use chlorinated lime and "not to spare the material ' 3 Rather, however, than using the field for growing vegetables he would prefer a plantation of young trees for three or four years. 4 He thinks it should not be used as a pasture for at least three years, "after which it would probably be entirely safe" The Board of Agriculture has issued a leaflet giving advice which can be obtained free of cost but it is said that farmers do not trouble to get it. The small holder is reputed to be most guilty of neglect, his excuse being that he cannot bear the loss of his cattle by compulsory slaughter. This perhaps is not the place to consider the matter in its economic bearings but surely a scheme of insurance, if need be compulsory, might be devised to meet such cases.

Lifts and Fires.

A correspondent of the *Manchester Courier* draws attention to an important point as to the position of the lifts in a building. It was *à propos* of an incident mentioned by Dr. Torrey, an American evangelist now visiting Manchester. The lift was placed in the well of the staircase. The fire began on the ground floor, so that when it reached the staircase escape from the upper floors was impossible by either the lift or the staircase. Though it would be more costly it would be safer to have a separate arrangement for the lift in another part of the building, as there would then be two possible ways of escape instead of one. The staircase in fires originating in the lower parts of a building serves too often as a flue with a strong draught.

Municipal Chemistry.

Mr. I. Carter Bell, who is the analyst for the county of Chester and for the county boroughs of Salford, Birkenhead, Congleton, Stalybridge, and Glossop, and chairman for the year of the Manchester section of the Society of Chemical Industry, gave an interesting address on Municipal Chemistry at the opening of the twenty-first session of the society on Nov. 6th. By municipal chemistry he meant the chemistry connected with all the chemicals required by a large corporation and all matters upon which the chemist of that corporation had to advise, including also all samples bought under the Sale of Food and Drugs Act. He showed how corporations lost large sums of money through not having the chemicals which they bought examined. He thought that there should be an adequate staff to work under the analyst and considered that if there were such an arrangement large sums would be saved. In reviewing the quality of food during the last half century he pointed out that while years ago the percentage of adulterated samples was 70, it was now only 1 in Salford and 3 in Cheshire and that at the present time the adulteration was almost perfectly harmless. He thought the work of analysts might be made more useful if a central bureau were established for the spread of information among them in connexion with their work. It appears that there are over 200 counties and boroughs that require analysts. He also urged that in technical schools and elsewhere special departments should be established for the training of chemists for the special work of municipal chemistry. In explanation of the necessity for the establishment of such a department he said that "during all the years he had been a public analyst he had never yet had a student fresh from college who had been of any use to him until he had been with him some little time."

Compensation for Death by Lightning.

Rather a curious question as to compensation for the death of a labourer by lightning came before Judge Bradbury on Nov. 12th. Two bricklayers were at work on a scaffold on new premises at Failsworth and were both killed. The widow of one claimed compensation under the Workmen's Compensation Act and, subject to the question of liability, the amount was agreed on as £300 At a former sitting of the court "a doubt arose whether the fact that the deceased man was working on a scaffold 23 feet from the ground made an appreciable increase in the risk of his employment as compared with working on the ground" and the case was adjourned for expert evidence. On the 12th Dr. C. C. Garrard, head of the testing and experimenting department at Messrs. S. Z. de Ferranti and Company's electrical engineering works, and Mr. J. M. Faulkner, an erector of lightning conductors, both considered that the position in which the man was working did increase the danger above that of working on the ground or in shelter. His honour gave judgment for the plaintiff with costs, but granted a stay of execution and consented to state a case for appeal. He thought the question was one in which it was desirable that there should be a decision of the higher court. Pending the decision of the appeal he directed that the respondents should pay the widow £1 a week on account.

Manchester and Salford Red Cross Society.

The annual meeting of the delegates of the Red Cross Society was held on Nov. 6th at the City Art Gallery. The report stated that the collections this year had reached a record amount (for this district)—namely, £4537 4s. 3d. The committee regards this as an indication that the work-people appreciate the efforts made to provide them with convalescent homes. Another important factor is that weekly collections are now made at the various works. To give one instance. At the Bridgewater collieries the collections in 1902 amounted to £54 while the nine months of the past financial year realised £100, and in the future it is expected to realise annually £150.

Manchester Guardians and Milk Dangers.

At a recent meeting of the Manchester board of guardians it was decided to send to the corporation sanitary inspectors a list of the contractors who supplied milk to the board, asking that the board should be informed if tuberculosis were discovered among the cows of any of the farmers in the list. A member of the board thought the farmers should be informed that cattle could now be insured against tuberculosis at a very moderate rate and that if the cows were insured and the farmers knew they would not suffer loss they would not try to conceal cases of tuberculosis.

Nov. 17th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

A Judge on Infanticide.

AT the Carmarthenshire assizes, held on Nov. 12th, Mr. Justice Bruce in his charge to the grand jury referred to crimes of infanticide, which he feared were becoming common, so that there was a danger of the crime being encouraged by false public sympathy. It was contrary, he said, to every principle of morals and every instinct of nature for a mother not to be careful to preserve the life of her offspring, and if infanticide came to be regarded as a light or venial crime the consequences to society would be deplorable. It was a high function of the law to protect all. The greatest were not exempt from its power; the least were not unworthy of its care and it would abdicate one of its chief functions if it did not exert itself to preserve the lives of innocent and helpless children. The particular case which called forth this protest of Mr. Justice Bruce was that of a farm servant who gave birth in a field to a child whose dead body was subsequently found in a pond. The evidence did not make it very clear as to whether there had been a separate existence and there was no concealment of the facts by the girl who declared that the child was stillborn and she was accordingly acquitted.

Weston-super-Mare Refuse Destructor.

The town of Weston-super-Mare is becoming increasingly popular not only as a seaside resort during the summer months but also as a place for permanent residence. The members of the urban district council have usually shown themselves to be fully alive to their responsibilities; the roadways are for the most part wide, well paved, and sufficiently scavenged, electric trams have been installed, a well-organised isolation hospital has been provided, and the water-supply is abundant and above suspicion. The council may now be congratulated upon its resolve to abandon the refuse tips which during recent years have been accumulating on the outskirts of the town and it is to be hoped that the small minority of district councillors who are opposing the provision of a destructor will not be able to influence local public opinion in opposition to those councillors who are evidently desirous that their town shall not be behind other health resorts in its sanitary equipment It is proposed to erect the destructor near the waterworks and to use the steam in connexion with the pumping engines There appears to be a little uneasiness in some quarters as to the depreciating effect upon the surrounding property which is exercised by the erection of a destructor. That there need be no cause for anxiety provided a proper type is selected may be easily demonstrated by a visit to neighbouring towns where destructors have been in operation for more or less lengthy periods.

Scarlet Fever Patients in Seaside Lodgings.

The proprietor of a lodging-house at Aberystwyth has recovered damages amounting to £21 from a person whose wife took a child to the house while in the convalescent but infectious stage of scarlet fever. It appears that one of the four children who went with their mother to the lodging-house was taken ill on the night of their arrival and was found on the next day to be suffering from scarlet fever. The medical man who was called in to see the child ascertained that one of the sisters was actually peeling and it was with respect to this latter patient that proceedings were taken. There can be little doubt that the large number of isolated cases of scarlet fever which are constantly occurring without any apparent contact with a previous case are to be accounted for by the thoughtlessness which permits infected children to travel from one place to another. It is extremely probable that this particular child may have infected others during the railway journey from Staffordshire to Aberystwyth.

University of Wales.

There was an interesting series of ceremonies at Cardiff on Nov. 13th in connexion with the University of Wales. A letter from the Chancellor, the Prince of Wales, was read congratulating the University on the record results of the year. The chairman (Sir Isambard Owen) stated that during the past year 141 degrees were granted, the highest number given in any previous year being 103. The ceremony of laying the foundation-stone of the University registry offices in Cathay Park was performed by Sir Isambard Owen, the senior deputy-chancellor. The mayor subsequently entertained the University court, the corporation, and the guests at luncheon. In the course of the afternoon degrees were conferred and Lord Kelvin was admitted to the honorary degree of D Sc. of the University of Wales. In the evening the Principal and Mrs. Griffiths held a reception.

Colston Day in Bristol.

Nov. 13th was observed in Bristol as Colston Day in the customary manner. In the evening the members of the various societies—the Dolphin (at which the Prime Minister was the guest of the evening), the Anchor, the Grateful, and the Parent—held their respective dinners. The collections for the various charities amounted to £4384, compared with £3589 in 1902.

Nov. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dr. Steevens' Hospital, Dublin.

SOME important changes have recently taken place in the medical staff of Dr. Steevens' Hospital. A meeting of the governors was held on Nov. 10th, when a letter having been read from Dr. H. C. Tweedy resigning his post of visiting physician to the hospital the same was accepted with much regret and it was unanimously resolved to ask Dr. Tweedy to accept the position of consulting surgeon to the hospital. A letter [illegible] his post [illegible] to the [illegible] THE LANCET will recognise the significance of the latter appointment. Mr. Hastings Tweedy is now, and will be for the next seven years, Master of the Rotunda Hospital, Dublin, which has only one rival in Europe in its special department.

The Milk-supply of Belfast.

Considerable attention has of late been called in the daily press of Belfast to the milk-supply of that city which seems to be sadly in need of greater supervision. At present it is not unusual to see milk-servers on their rounds carrying from the houses of their customers buckets or cans of household garbage—called locally refuse—while those who, like medical men, drive about the streets constantly meet country carts with manure from city stables wending their way home with empty buttermilk barrels on the top. Again, in many parts of Belfast at certain times, usually the evening, one sees collections of milk-carts, the drivers of which are borrowing from one another milk, while all the time the innocent buyers of milk imagine their supply comes from the same uniform source. The corporation officials take no notice and as far as the public health committee of Belfast is concerned it never initiates any reform but contentedly waits until it is literally shamed by a public outcry into doing something and then what it does propose, as in the case of dealing with the treatment of consumptives, so slightly touches the main question that it is generally ridiculed in the newspapers and finally defeated in the city council.

The Polluting of Belfast Lough.

At a meeting of the Castlereagh rural district council on Nov. 10th public attention was again called to the horrible condition of the foreshore at Cultra on the right bank of Belfast Lough. Since August it appears that several cases of typhoid fever—all of bad type—have occurred in the neighbourhood and as in each case there was a different milk- and water-supply it is inferred that the bad drainage was responsible for an endemic condition of this disease. The abominable smell from the foreshore was so bad that it was stated that many families have left the district and sore throats of a diphtheritic type have been prevalent among the residents. The contention is that all this disease arises from the circumstance that the sewage of Belfast is discharged unpurified into the Lough and that the corporation of that city has failed to provide bacteria beds (as it is obliged by Act of Parliament) for the purification of the city sewage. A motion was passed requesting the Local Government Board to order a local inquiry to be held into the cause or causes of this nuisance on the foreshore of the district so that it may be found out by whose act or default the nuisance is created and the steps which should be taken for dealing therewith.

Outbreak of Typhoid Fever at Malin Head.

An outbreak of typhoid fever (17 cases) has taken place at Cullcort, near Malin Head, and attention has been drawn at the Innishowen rural council to the importance—as bearing on this epidemic—of enforcing the law in regard to the odious practice—still prevalent there—of keeping pigs in dwelling-houses.

Outbreak of Small-pox in Belfast.

On Oct. 10th a man named Moore, who had spent four days in a model lodging-house in Glasgow (from which several cases of small-pox have been reported in that city), returned to Belfast. On Oct. 20th, while at work in a large establishment in Belfast, he suddenly sickened, went home, and on Oct. 26th made his way to the Union Infirmary, when the eruption, now much faded, was diagnosed, and he was promptly isolated and sent to the small-pox block at Purdysburn, near the asylum. As a result five cases of small-pox have arisen and there are six "contacts" at the intercepting hospital. All the cases except the last reported on Nov. 14th (the patient being a brother-in-law of the first case) are mild but in this, the most recent case, the disease has assumed a severe type, the rash being confluent.

Nov. 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The School of Colonial Hygiene at Marseilles.

AT a recent meeting the municipal council of Marseilles voted a sum of 180,000 francs for a staff college of hygiene for colonial troops. The college will be installed in the Pharo, in that portion of the building hitherto used by the School of Medicine. The early expenses will be defrayed by the town which will also contribute to the general expenses of the school by giving 20,000 francs annually for the first five years. At the sixth year this grant will be reduced to 15,000 francs. The War Office will look after (1) the salaries of the staff in authority; (2) the salaries of the various employés; (3) any hospital expenses which may be incurred by colonial soldiers; (4) any payments which may be due to civilian nurses sent for service at the college by the hospital administration (these payments will be calculated on the basis at present obtaining in mixed military hospitals); (5) the keeping up of a stock of drugs, chemicals, and reagents which may be necessary for teaching; and (6) the general expenses of the college over and above the maximum sum allowed as a grant from the town. The municipal council of Marseilles has every reason to consent to bear these burdens for its city is one eminently marked out to be the centre of a school for teaching colonial hygiene.

A View of the Digestive Journey.

At the meeting of the Society of Biology, held on Oct. 31st, M. A. Sicard and M. C. Introit gave an account of a method by which they had tried to study systematically the movements of the digestive tract in man. They used an ordinary gelatin capsule 15 millimetres long and six millimetres in breadth which was filled with a salt of bismuth and then dipped into collodion. This gave the capsule a coating which was almost unaffected by the digestive juices. It thus became possible by means of radiography to define the various places which the capsule occupied after being swallowed. The capsule was swallowed fasting and was seen to remain in the greater curvature of the stomach for about half an hour. Nothing more was then seen of it for about eight hours when it was located in the cæcum. This was due to its traversing the seven or eight metres of the small intestine at too rapid a rate—namely, some 25 centimetres in the ten or 15 minutes of exposure—to leave an impression on the sensitised plate. It was found to remain a long time, four or five hours, at the level of the cæcum and then passed through the ascending colon in one or two hours, the transverse colon in from two to three hours, the descending colon in from three to four hours, and finally between the twentieth and the twenty-fourth hour came to rest in the sigmoid flexure ready to be expelled. The interest of this test from a physiological point of view can be easily seen and the method will doubtless find many applications.

The Tuberculosis Commission.

The President of the Council, M. Combes, is occupied with setting on foot the permanent committee for the prophylaxis of tuberculosis, a committee due to the Minister of the Interior. M. Combes has decided that the function of the committee is merely to occupy itself with the protection of healthy individuals against disease and that it shall leave to others the care of the sick. M. Bourgeois has been discoursing on social duty as regards tuberculosis and demonstrates how society ought to protect the individual against his own ignorance and against all causes which may act unfavourably upon him from outside, whence the germ of tuberculosis may spring. After having enumerated these causes M. Bourgeois as the conclusion of his discourse lays down a scheme of work. The committee is divided into eight subcommittees—namely: (1) education (Presidents, M. Buisson and Dr. Peyrot); (2) food (Presidents, Professor Debove and Professor Manoury); (3) housing (Presidents, M. Jules Siegfried and M Germain); (4) personal environment (Presidents, Dr. Grancher and Dr. Albert Robin); (5) general environment (Presidents, Professor Brouardel and Professor Masson); (6) conditions of work (Presidents, M. Millerand and Dr. Emile Roux); (7) social defences against outbreaks of disease (Presidents, Dr. Bouchard and Dr. Armaingaud); and (8) ways and means (Presidents, M. Strauss and Dr. Villejean).

Marmorek's Antituberculous Serum and the Pasteur Institute.

M. Marmorek, the head of the staff of the Pasteur Institute, was announced to read a paper at the Academy of Medicine on Nov. 10th but to the surprise of everyone no paper was forthcoming. It appears that the directors of the institute had notified to M. Marmorek that they did not intend that the institute should identify itself with any work of his which was carried out not under their control and that they preferred that he should not read his paper unless he resigned his connexion with the institute. A similar situation occurred at the recent Congress of Hygiene at Brussels and then M. Marmorek determined not to read his paper. But at the Academy of Medicine the members of the institute held a meeting in one of the committee rooms and decided again to put the alternative before M. Marmorek who this time decided to read his paper and to give up his post. The facts are grave but merit close attention. Many years ago M. Marmorek brought out an antistreptococcic serum which did not come up to the expectations formed of it. Owing to M. Marmorek's official position at the institute which prepared and sold this serum its failure brought discredit on all the preparations of the institute. Certain members of the medical profession who decry all serum treatment and are always rejoiced when any failure occurs with antirabic serum, accused the institute of being merely a serum shop which made large profits at the expense of the pharmaceutical chemists. The real truth is that the institute, that admirable nursery of scientific workers, never has a balance on the right side without the help of private charity. Its members live like Benedictines, draw very small salaries, and entirely give up private practice The recent attacks have evidently affected them to a certain degree and after the failure of the antistreptococcic serum, for which the institute was in no way responsible, they naturally wished to leave the responsibility of the new serum entirely with its creator, not that they necessarily consider that it is of no use, but they wish M. Marmorek's name alone to be associated with it and not that of the institute. On Nov. 17th M. Marmorek read his paper.[1] In brief, he said that he had formed the opinion that the tuberculin of Koch was not the real toxin fabricated by the bacillus tuberculosis but an accessory substance which excited the bacillus to secrete that toxin. He now considered that he had been able to isolate the true toxin from cultures of the bacillus. This toxin he injected into horses and finally obtained a serum containing either the attenuated toxin or an autotoxin secreted by the horse. This he tried upon animals and was enabled to render them refractory to large doses of a virulent culture of Koch's bacillus. He then tried it on human beings. In cases of tuberculous meningitis he obtained no success except that the symptoms became less grave and he is therefore of opinion that if used early the serum might exert a favourable action. In cases of pulmonary tuberculosis the patients improved. In six cases of tuberculous pleurisy the effusion rapidly disappeared. In surgical tuberculosis patients suffering from tuberculous glands and tuberculous caries of the bones recovered under the serum treatment alone. M. Marmorek concluded by saying that he took the whole responsibility for these statements on himself. The communication was, however, somewhat coldly received by the Academy and astonishment is no longer expressed that *M. Roux* and *M. Metchnikoff* have declined to associate themselves with M. Marmorek in these experiments.

Banquet to Dr. J. Rivière.

Dr. J. Rivière, the physico-therapeutist who was recently decorated with the Legion of Honour, was fêted recently at a banquet at the Hôtel Palais d'Orsay, Paris, at which the Deputy for Réunion, M. Brunet, presided. Dr. Rivière, who in spite of his French name is an English subject, is one of the foremost living authorities in physicotherapy and it will be remembered that he read a paper not long ago on the treatment of cancer before the Medical Congress held at Madrid. The gathering was a brilliant success and a number of members of the Academy of Medicine were present, including M. Lancereaux, the President, to whom M. Brunet paid a warm token of esteem in his speech. Dr. Rivière was brought up in the Mauritius and was educated at the lycée of Réunion, under M. Combes, a letter from whom was read by M. Brunet. Other speakers were M. Lancereaux, Dr. Mazery, Dr. Bérillon, M. Edgar Gallet, Dr. Besançon, Dr. Foveau de Courmelles, and Dr. Cogrel, all of whom united in expressing their esteem and affection for Dr. Rivière, who ended his speech of thanks with these simple words: "To all, then, both absent and present, my masters, fellow students, compatriots, and friends, I offer my heartfelt thanks"

Nov. 18th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Goldberger Prize.

DR. ALFRED COHN, *privat-docent* of histology in Prague, has been awarded the Goldberger prize for his researches on chromaffin cells and paraganglions, his investigations having led to an improved knowledge of the sympathetic nervous system and internal secretions.

Argentum Colloidale in Sepsis.

Dr. Loebl in a communication to the Gesellschaft der Aerzte reported some encouraging results in the treatment of sepsis and thrombo-phlebitis with Credé's argentum colloidale administered as a clyster. He used this colloid silver solution—"collargol," as it is called—twice a day for a week in quantities of from 15 to 30 centigrammes in 75 grammes of distilled water. The clyster has the same effect as an intravenous injection but is much easier to employ and is free from all risk. This treatment in apparently hopeless cases of sepsis led to many recoveries.

The Causes of the Hæmostatic Action of Gelatine.

Dr. Moll of Prague has found that the intravenous or subcutaneous injection of gelatine increases the amount of fibrinogen to a maximum of twice the normal. Gelatine also causes agglutination of the red blood corpuscles. The increased amount of fibrinogen in the blood, together with [illegible] gelatine when [illegible] into the blood [illegible] a prophylactic measure some days before an expected loss of blood

---

[1] We hope shortly to publish this paper in full.—ED. L.

Appointments

Dr Hermann Schloffer, extraordinary professor in Prague, has been appointed ordinary professor of surgery in Innsbruck. Dr Biernacki has been recognised as *privat docent* of experimental pathology in Lemberg

Treatment of Omphalocele with Injections of Paraffin

In the treatment of infantile omphalocele Dr Escherich uses the method of paraffin injections, first described by Gersuny The surgeon replaces the contents of the omphalocele with the fingers of the left hand and in his right hand he holds a syringe with a curved needle containing eight cubic centimetres of paraffin having a melting point of 39° C He thrusts the needle into the middle of the omphalocele so that the point of the needle being directed upwards should be free in the cavity The assistant then injects the fluid paraffin into the omphalocele and the evaporation of chlorethyl is used to make it solidify This method has been used in 30 cases with very encouraging results

The Medical Profession in Vienna and the Landtag

In my last letter I mentioned that the Landtag had prohibited experiments on animals in the University Hospital which together with any animals kept therein for experimental purposes, is under its control The professors asked the help of the Minister of Public Instruction and his decision was as follows ' The professors are under the control of the Ministry, only the rabbits are under the control of the Landtag Therefore the Landtag cannot prevent the professors making any experiments which they please, it can however, confiscate the rabbits From this it was clear that the Minister did not wish to champion the cause of science so the professors and students held a numerously attended meeting in the university, protested against the suppression of scientific research and after the meeting some riots occurred in the streets and many students were arrested At the next sitting of the Landtag the leaders of the anti Semitic party renewed their accusations against medical science and charged the professors with cruelty to animals and with ill treatment of patients. Dr Lueger, the well known mayor of Vienna afterwards accused Professor Pollitzer, Professor Kolisko and Professor Obersteiner of dishonesty because they had taken some anatomical material from necropsies made in hospitals and asylums which belonged to the city of Vienna and not to the State The governor of Lower Austria did nothing to assist either the medical profession or the university, on the contrary he supported the accusations against the medical men and attacked the association of physicians Disgusted by these proceedings on the part of the governor and the members of the anti Semitic party uncommon even in Austria the association passed a vote for its dissolution These events are causing great excitement in university circles and not less among general practitioners, the newspapers are filled with letters of protest emanating from the aggrieved professors and other leading medical men. The status of the general practitioners is seriously affected because public confidence in the profession in Vienna is much diminished the middle classes being mostly partisans of the anti Semitic party The first sign of this discredit was noticed lately by a surgeon in the State Hospital in Vienna A man brought his child for medical aid and on being told that it suffered from appendicitis and could only be saved by an immediate operation he refused his consent saying "My child is not a rabbit for you to torture ' The child died on the next day The speeches delivered in the Landtag against the medical faculty and the general practitioners are printed by the Landtag and distributed free of cost in order to stir the people up against the medical profession Some periodicals contain pictorial representations of cruelty to animals and ill treatment of patients on the part of the medical men As an example of the value set by the anti Semitic party on science particularly medical science a quotation may be given from Dr Lueger's speech on the medical professors He said "The professors are very conceited, I have said to all the professors that if their science is of any value they should be able to make artificially something like grass to feed cows, if not then their science is worthless '

Changes in the Central Nervous System produced by Whooping cough

Dr Rudolf Neurath making researches on whooping cough found that very various clinical symptoms were produced by it, including cramps and paralysis in the motor nerves and muscles, convulsions palsy of cerebral spinal, or peripheral origin psychoses and neuroses, disturbances in the functions of special sense meningitis, and sometimes sclerosis disseminata multiplex Post mortem hæmorrhage in the brain or meninges, together with some other lesions, may be found Dr Neurath found in 16 out of 17 investigated cases that the pia mater and arachnoid were very much thickened (more than six times as thick as normal) a new proliferation of connective tissue and lymphocytes penetrating the meninges, there were also many hæmorrhages in the pia mater and between the meninges and the brain He was able to see in the grey substance of the brain dilatation of the lymphatics, œdema hæmorrhages of varying intensity hyperæmia, and accumulation of white blood corpuscles along the vessels In some cases œdema of the meninges preponderated and in other œdema of the brain It was quite impossible to find micro-organisms either microscopically or by culture methods There was a surprising correspondence between the clinical symptoms and the result of the histological examination of the meninges and the brain Cases with highly developed nervous symptoms convulsions, phenomena of brain pressure and somnolency showed the above described histological changes especially the accumulation of new cells in the meninges

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Bubonic Plague

A MAN employed as a deck hand on the steamer *Innamincka* trading between Melbourne and North Queensland died from plague at Townsville on Sept 7th. The case is of some interest in regard to the possible mode of infection The vessel left Sydney on August 29th and arrived at Brisbane on August 31st The patient is reported to have been taken ill on Sept 2nd while the vessel was between Brisbane and Rockhampton At Townsville he was landed and died on the next day A plague infected rat was caught on August 6th and a plague infected mouse on August 11th about 200 yards from the wharf at which the *Innamincka* was berthed in Sydney Thus the patient may have been infected in Sydney, or on board by rats which went on the vessel at Sydney, or at some other plague infected port The Board of Health is making every possible endeavour to investigate the case and to find out the exact method of infection in this case —A Chinaman has died from plague at the Perth Hospital —The President of the Board of Health of New South Wales (Dr J Ashburton Thompson) has published an elaborate report on the second or 1902 outbreak of plague in Sydney Prefacing his report by the statement that the events of the epidemic of 1902 justify and enforce the advice which was given in the report on the outbreak of 1900 Dr Ashburton Thompson proceeds to discuss the causes of the maintenance and spread of plague The observations of 1900 that the epidemic was not caused by direct communication with the sick, nor by diffusion of infected articles nor by place infection have been confirmed and amplified The evidence in support of the theory that the rat is the sole source from which infection is communicated to man has been largely supplemented and the attention of the authorities is now being given to determine the species of the fleas which infest rats in this part of the world, to variations in their frequency on rats at different times, and to examining into their ability to bite man The President of the Board of Health concludes the preface to the report by emphasising the fact that the promise of safety for the future lies neither with attempts to prevent the importation of plague infected rats which must fail from time to time, nor with attempts to exterminate the rats infesting the locality to be defended, which have been found to be practically impossible, though both of these measures have their valuable uses The really safe course lies in habitually excluding rats from inhabited premises Dealing with the history of the epidemic the report states that it declared itself with the third case in January, 1902, and concluded on June 8th of the same year. There were 139 cases, of which 39 ended fatally. Of the 139 cases, 132 occurred among whites, 34 proving fatal, and seven cases among male Chinese, of which five ended fatally. No public and very little detail inoculation was done during this outbreak. Two alone of the persons attacked asserted that they had been inoculated. Out of 286 houses which harboured the plague in 1900 only eight again harboured cases in 1902 Dealing with the origin of the epidemic, the only hypotheses worth serious examination in the opinion of the Board of Health are the two following: either the epidemic depended on a recrudescence of the epizootic of 1900 or upon a second epizootic set going by newly imported plague-infected rats. As to the former, the health department had reason to believe that the epizootic of 1900 died out in the course of that year, but the evidence gathered was insufficient to establish the fact. Still, the recurrence was apparently too long delayed to have been a recrudescence and the balance of evidence at Sydney appears to tell in favour of reimportation. Practically, the local authorities have decided that while there is no pathological evidence that man is infected by feeding there is abundant testimony that he is usually infected by inoculation and that the agent between the rat and man is the flea.

Tuberculosis in New South Wales.

At a meeting of the Actuarial Society of New South Wales a paper on Tuberculosis was read by Mr. J. B. Trivett. As the result of a statistical investigation he concluded :—

1. That the death-rate from tuberculosis in New South Wales has been a serious factor [illegible].

2. That this [illegible] ages, the rates in the adult age g[illegible] the general tuberculosis rate.

3. That for males the rate progressively increases with age for all the wage-earning ages, and for females increases to age 35, and thence diminishes.

4 That in each age group the intensity of the tuberculosis risk has lessened with the progress of time, until on the whole it is about two-thirds of the risk apparent 15 years ago.

5. That the excessive death-rate from tuberculosis in the metropolis has been the main cause of the high rates of former years and the reduction of the rates for the State generally has been entirely due to the lowering of the metropolitan rates.

6 That the risk for the country districts has been practically constant throughout and any further relief in the general rate must apparently be expected from a continued improvement in the metropolitan rate, which is still 40 per cent. higher than that of the country for males and 50 per cent. higher for females.

7. That, arguing from the constancy of the country rates, we may fairly expect to be able to reduce the rate for the State to at least 1 per 1000 for males and to three quarters of one per 1000 for females of all ages, the present country rates.

The Supervision of Milk.

The chairman of the Board of Health of Victoria (Dr. D. A. Gresswell) has drafted a Bill for the supervision of milk to be read and construed as part of the Health Act. It provides for the constitution of "milk areas" to which the Act shall apply. Municipal bodies are to be empowered to prohibit the keeping, grazing, or milking of cows in any part or parts or the whole of their district and may determine by by-laws the distance from any house or from any offensive trade establishment, as defined by the Health Act, 1890, within which no cow shall be housed or kept and no milking be carried on; and any council may prohibit the keeping of any cow for production of milk for sale that is habitually depastured on any street, road, or thoroughfare or that has unrestricted access to any street, road, or thoroughfare owing to the absence of effective fences. Dairies are to be registered and milk produced beyond the milk area is not to be sold within it without a licence. Plans and specifications of new dairy farms or dairies or of alterations in regard to those already in existence in a milk area must be submitted to the council for the district and must be in accordance with by-laws which the councils are empowered to make. All dairymen within a milk area are required twice a year to have examination made by a veterinary practitioner as to the state of health of the animals, the nature of the food and water-supply, and as to any prescribed condition at such dairy farm, and must obtain a certificate setting forth the result of such examination. The board in regard to any portion of Victoria, and any council in regard to its municipal district, may require veterinary surgeons to report concerning every animal that, in their opinion, there are reasonable grounds for believing to be affected with any of the following diseases: anthrax, tuberculosis, contagious pleuro-pneumonia, foot-and-mouth disease, rinderpest, tick fever, bubonic plague, symptomatic anthrax, or black quarter, cow-pox, swine fever, infectious abortion, or with any prescribed disease. Dairymen are also required to report to the local councils the occurrence of diseases amongst their animals and to isolate animals affected with disease. Milk from diseased cows may not be offered for sale and dairy farms and dairies may be prohibited from being used for the production of milk for sale if the board or the council, as the case may be, is of opinion that such milk is injurious to health or unwholesome. Dairymen are required also to notify the councils of disease in their household or amongst their employés and to prevent contamination of milk by persons affected Milk and milk products are to be sold under their proper designations and nothing foreign is to be added to milk for sale.

Lunacy in Victoria.

The annual report of the inspector-general of lunatic asylums in Victoria has been presented to Parliament and a Bill for the amendment of the Lunacy Act has been drafted and circulated by the Chief Secretary of Victoria.

Charges against Dr. W. Ramsay Smith.

The board appointed to inquire into the charges against the coroner and inspector of anatomy at Adelaide—Dr. Ramsay Smith—mentioned in my last communication, has held numerous meetings and investigated the charges most minutely. The board reports: "We dismiss all the charges and in answer to the complaint report that Dr. Smith has not been guilty of any conduct rendering him unfit to remain in the civil service." The board finds that a mistaken view was taken of the law and that the local Anatomy Act is similar to the Imperial Act. The purpose of the legislation had been to facilitate and to regulate the study of anatomy, and it was the duty of a medical man to obtain practise on dead bodies in the interest of science, and medical men, whether private or official, had the right to practise post-mortem examinations. The board considered that the charges against Dr. Smith for breaches of the Anatomy Act, by reason of his not being licensed, had failed. It was part of his duty, in the ordinary course of his medical practice, to remove parts of the body from the living as well as from the dead. How much or how little should be removed was a question of judgment and good taste. Dr. Smith, in removing parts of the bodies, did so either with the consent or non-objection of relatives. On these grounds the board said that Dr. Smith had committed no offence. Dr. Smith was justified in removing the skeleton of an aboriginal. He did no act forbidden by law but was indiscreet and allowed his zeal in the cause of science to outrun his judgment. Dr. Smith is also exonerated for taking the Chinaman's body from the lunatic asylum and sending the head abroad for museum purposes. With reference to the charge that, in his position of coroner, Dr. Smith took improper advantage of certain bodies, the board held that his duty as coroner ceased on giving his warrant for the burial and the charge of mutilation before burial was not proved. The board points out that Dr. Smith did nothing for gain or personal benefit and that his gratuitous labour in connexion with criminal cases had been great. Consideration of the experimental work he had performed as a medico-legal expert should shield him from blame at the hands of the Government. In the House of Assembly the Premier, in reply to a question, said that the Government had had very little time to consider the report of the Ramsay Smith Board of Inquiry but it had decided to advise the Governor to reinstate Dr. Smith in the offices of coroner and chairman of the central board of health. The office of physician to the isolation ward in the hospital the Government proposed to abolish as it was not necessary to renew it. In order that no injustice should be done to Dr. Smith the salary paid for that position would be transferred to his position as coroner. The positions of inspector of anatomy and vaccination officer the Government intended to suggest that Dr. Smith should relinquish. With regard to private practice Dr. Smith had only a consulting practice and the Government considered that this did not affect his position but it would further consider it. The Government would pay all reasonable costs of the inquiry.

Oct. 5th.

SUPERANNUATION ALLOWANCE. — Mr. James Williams, who has recently resigned the post of district medical officer to the Holywell (Flintshire) union, after 50 years' service, has been granted a superannuation allowance.

Obituary.

SIR CHARLES NICHOLSON, BART., M.D., D.C.L., LL D.

THE life of this remarkable man, who died on Nov. 8th, bridges over a considerable period of history, relating especially to British colonial affairs, for he had arrived within a few days of his ninety-fifth birthday.

Charles Nicholson was born at Bedale in Yorkshire. He studied medicine in Edinburgh and took his M.D. degree there, presenting his inaugural thesis, "De Asphyxiâ," in 1833. He was probably the last survivor of the graduates of that year who numbered 109 Amongst his fellows on that list were Scott Alison, Martin Barry, J. Risdon Bennett, [illegible] who afterwards became eminent [illegible] Nicholson went out to Australia [illegible] property belonging to his uncle near Sydney, then a very small town, where he practised medicine for some years. He speedily identified himself with the social and political interests of the colony and carried on his studies assiduously in classical and general literature, accumulating a very fine library. He took a large part in promoting higher education and was one of the chief founders of the University of Sydney. In 1843 he appears to have abandoned practice and entered parliamentary life on election as a member of the first legislative council of the colony. He was on three occasions chosen for the office of Speaker between 1845 and 1856. In 1854 he was elected the first Chancellor of the University, having been knighted by patent in 1854 In 1859 he was created a baronet. On leaving the colony, about 1864, he travelled in India and finally settled in London. He married in the following year a daughter of the late Mr. Keightley, well known as the registrar of the Charterhouse. Always deeply interested in matters relating to New South Wales he carried on his studies over a wide range of subjects. He received the honorary degree of D C.L. from Oxford and that of LL.D. from Cambridge, and late in life the LL.D. of Edinburgh, his old University. On leaving London some 20 years ago he retired to the Grange, Totteridge, in Hertfordshire, where he entertained many of his friends. When he was 90 years of age his house was burned to the ground but nothing daunted he rebuilt it on its former lines and resumed his former studious life. His last illness was of a few days' duration. The funeral took place on Nov. 12th in Totteridge churchyard and was largely attended by many colonial representatives and old friends. By desire of the Principal the University of Edinburgh was represented on the occasion by Sir Dyce Duckworth. Sir Charles Nicholson is succeeded in the baronetcy by his son, Charles Archibald, who has already secured a leading position as an architect. Sir Charles Nicholson's career affords one of not a few instances in which members of our profession have risen to eminence in other walks of life and the history of such lives is always the same, telling of high purpose, indomitable industry, wide capacity, and self-effacement. We may, indeed, be proud to count such men in our ranks. Of this noble career we may well say, "*Finis coronat opus.*"

Medical News.

UNIVERSITY OF CAMBRIDGE.—The Special Board for Medicine of the University of Cambridge has just presented to the Vice-Chancellor a report recommending the establishment in the University of an examination and diploma in tropical medicine and hygiene. The proposal is approved by the State Medicine Syndicate which is prepared to undertake the management of the scheme and the conduct of the examination. The Special Board has accordingly recommended that certain new regulations be added to the ordinances relating to the examination in State Medicine. The regulations are, in short, that an examination be held once or, if expedient, more than once a year; that 12 months shall have elapsed after the candidate has attained a registrable qualification; that a statement of conditions of admission to the examination be published from time to time; that the subjects be the nature, incidence, prevention, and treatment of epidemic and other diseases prevalent in tropical countries; that a candidate passing satisfactorily be entitled to a diploma which is set forth in the board's report; and that candidates pay certain fees. Supplementary regulations are also suggested to the effect that candidates shall present evidence that they have attended a course of laboratory instruction in tropical diseases, a course of clinical instruction in tropical diseases, and a course of instruction in hygiene applicable to tropical countries. Candidates' dissertations and memoirs, if any, concerning tropical diseases may be presented and will be taken into account in determining the result of the examinations. The examinations will be partly in writing, partly oral, practical, and clinical. This departure is approved by the Colonial Office; and it will be noticed that in a recent Colonial Office circular it is proposed that all medical men whose fees are paid by Colonial Governments shall before proceeding to their appointments be required to pass an examination or to obtain a certificate of proficiency in tropical medicine. The scheme was also approved by the late Secretary of State for War who stated that, due regard being had to the exigencies of the service, no obstacle would be placed in the way of officers of the Royal Army Medical Corps desirous of obtaining the new diploma.—Professor Howard Marsh has been elected a professorial Fellow of King's College; he was admitted to the M.A. degree *honoris causâ* on Nov. 12th —Dr. W. M. Fletcher has been appointed Demonstrator of Physiology —At a Congregation on Nov. 12th the following were admitted to medical degrees:—

[illegible] sus; and J. C. Mathews, [illegible]

Under the new Act of Parliament a general committee was on Nov. 16th elected to adminster the affairs of Addenbrooke's Hospital. Eight members are chosen from each of the groups known as the borough, the county, and the University governors respectively. Dr. P. W. Latham was elected as a borough member and Professor T. Clifford Allbutt and Dr. D. MacAlister were chosen as University members.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS—The following have received the Diploma in Public Health after passing the necessary examination:

Hono[illegible]
Pass [illegible]
H. [illegible]
Edi [illegible]

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the stated meeting of the President and Fellows held on Nov. 13th the following were admitted Licentiates in Medicine of the Royal College of Physicians of Ireland:—

Mrs. Agnes Forbes Saville, M.D., and Thomas Gillman Moorhead, M.D.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—DENTAL EXAMINATION.—The following candidates have passed the final examination for the Licence in Dental Surgery:—

W Hopton, Manchester; H. J. Anderson, Galway; B. D. Black, Dublin; L. C. Pelissier, Clonmel; W. V. Pericho, Cork; and J. Smith, Dublin.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. V. Schmieden and Dr. K. Reifferscheid have been recognised as *privat docenten* of Medicine.—*Giessen:* Dr. K. Kisskalt has been recognised as *privat docent* of Hygiene.—*Königsberg:* Dr. Bernhard Rosinski, *privat-docent* of Gynæcology, has been granted the title of Professor.—*Würzburg:* An out-patient department for mental cases has been opened in connexion with the University clinic, under the care of Professor Rieger and Dr. Weygandt.

LITERARY INTELLIGENCE.—It has been decided by the New Sydenham Society to devote almost the whole of its income during the next five years to the production of an "Atlas of Clinical Medicine, Surgery, and Pathology." Of this work eight parts are now ready—viz., Parts I. to IV. for 1901 and Parts V. to VIII. for 1902. Part IX. commences the issue for 1903 It will comprise the subjects of eruptions due to arsenic, urticaria pigmentosa, and leprosy. The council states that if adequate support is given by the profession the rate of issue may easily be doubled. Any member subscribing for himself in one sum five guineas as annual subscriptions beginning with the year 1901 will be entitled to receive the works for the six years 1901–06. All communications respecting the literary part of the work, suggestions, offers of drawings, and the like, should be addressed to the honorary secretary, Mr. Jonathan Hutchinson, at the Polyclinic, 22, Chenies-street, Gower-street, London, W.C.

PRESENTATION TO A MEDICAL PRACTITIONER.—Following on the annual meeting of the Perthshire branch of the British Medical Association the President, Dr. J. Liddell, presented Dr. D. H. Stirling with his portrait on behalf of the subscribers who were his medical friends and colleagues. The portrait is a three-quarter length by Mr. C. S. Sellar, R.S.W., and bears an inscription commemorative of Dr. Stirling having attained his jubilee as physician and surgeon.

EXTIRPATION OF THE UTERUS.—The death is announced of Dr. Karl Martini, a gynæcologist of Breslau who, it has been stated, was the first to remove the entire uterus for cancer. This statement must, we think, be incorrect. The first extirpation of the uterus, whether for cancer or not, was undertaken by Andreas da Cruze as far back as the year 1560, while coming down to times in which diagnosis was further advanced Langenbeck in 1813 and Sauter in 1822 both removed the entire uterus.

SWANSEA AND DISTRICT MEDICAL PRACTITIONERS' ASSOCIATION.—The report of the council of this association for the year 1902–03, the first year of its existence, has just appeared. Among the items of work successfully carried out by the association are the following. A request was sent out to various friendly societies for an increase in contributions. The friendly societies at first demurred and intimated their intention of forming a medical aid association. A conference was called at which the situation was discussed and in the end an agreement was arrived at by which the friendly societies agreed to the demands, slightly modified, which had been formulated by the medical men. At this time the local guardians of the poor sent out a circular with reference to vaccination. The association took the matter up and an arrangement was arrived at which was satisfactory both to the guardians and to the medical men. On various occasions the association has successfully arbitrated in disputes between two medical men. The association proposes during the coming year to consider the question of amalgamation with the Swansea branch of the British Medical Association.

HOSPITAL ACCOMMODATION IN SOUTH LONDON.—The Earl of Dartmouth, President of the Miller Hospital and Royal Kent Dispensary, Greenwich-road, is appealing for a sum of £5000 before the end of the year, to add to £2600 which the hospital received from the Coronation Fund raised in Greenwich, in order nearly to double the present accommodation of the hospital which is the only general hospital between Greenwich and London Bridge. At present the hospital has 25 beds which Lord Dartmouth says are invariably full and he wants to add another 20 beds. The hospital has a large number of out-patients and attends to a great many casualties and this is where its chief work seems at present to lie. The large hospitals, says Lord Dartmouth, are so well known that their wants are continually before the public and he desires earnestly to plead for a small institution quietly carrying on similar useful work. Subscriptions may be sent to the secretary, Mr. James Marks, at the hospital or may be paid to the London and County Bank, Greenwich branch. We would add that we hope that the appeal will be successful and although Lord Dartmouth states that little in this way can be done in the immediate neighbourhood, we should certainly like to see the workmen in some of the factories in and near Greenwich subscribe more largely than it appears they do at present as compared with, say, Poplar, another poor neighbourhood, unless it be that the workmen subscribe individually in Greenwich and not collectively. We think that when a hospital is local and well conducted it should appeal more to local philanthropy and should be able to command local support more than is the case with a large metropolitan hospital where the patients come from all parts. Why should not the inhabitants of Greenwich and Deptford be as proud of their Miller Hospital as of their famous Greenwich Hospital and Deptford Cattle Market? In fact, the Miller Hospital should be made a monument of local enterprise and a thing for the residents to be proud of, and the local Coronation Fund shows what they can do when they try.

THE SANITARY INSTITUTE.—Mr. Thomas W. Cutler, F.R.I.B.A., has been elected treasurer of the Sanitary Institute in succession to the late Dr. W. H. Corfield.

A CENTENARIAN.—Mr. A. F. Whatley, of Cirencester, attained the 100th anniversary of his birthday on Oct. 27th.

THE ZENANA BIBLE AND MEDICAL MISSION.—This body has been asked to undertake a new medical mission in India. The Zenana Hospital was built by a wealthy Hindoo lady some years ago and has been hitherto under the care of a committee. It has more than once been closed for the want of an efficient medical officer and the committee has now handed the building over to the Zenana Bible and Medical Mission. The society is consequently advertising for a qualified lady to act as medical resident. Further information can be obtained from the secretary, 2, Adelphi-terrace, W.C.

CHARING CROSS HOSPITAL.—The new Levy ward at this hospital was opened on Nov. 13th by Miss Matilda Levy, the founder, in the presence of a number of relatives and friends. This ward, founded in 1885, contained originally five beds, all of which were endowed in memory of late members of the Levy family. The ward in the new building contains 12 beds and, like its predecessor, is intended primarily for the reception of female patients of the Jewish faith, though it is not restricted to them. Miss Matilda Levy has endowed three more beds in memory of members of her family who have died since the previous endowment.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO-ROAD, S.E.—This hospital, which was founded in the reign of George III., is now in the course of reconstruction, reorganisation, and enlargement. The board is in hopes of establishing cots, and if possible entire wards, to be supported by various public bodies. Owing to the fact that the new Union Jack Club will shortly be erected in the immediate vicinity it hopes, with the assistance of the various London corps, to establish a military ward to be devoted to the sick children and wives of the rank and file, the name and regimental crest of each regiment being fixed at the head of each cot. 630 shillings, or 30 guineas annually, will support a cot, or the capital sum of 1000 guineas. Already one individual has generously promised to endow a cot on condition that five others will do the same.

Births, Marriages, and Deaths.

BIRTHS.

ABRAHAM.—On Nov. 14th, the wife of Dr. P. S. Abraham, of Henrietta-street, W., and Oakhurst Orpington of a daughter.

HELM.—On Nov. 11th, at Munslow, Craven Arms, the wife of William A. Helm, M.B., of a daughter.

MASON.—On Nov. 10th, at Cumberland House, Somers-road, Southsea, the wife of W. Blaikie Mason, M.R.C.S., F.R.C.P. Lond., of a daughter (stillborn).

DEATHS.

COLBORNE.—On Oct. 30th, at Peterhurst, Clevedon, Sarah Ann, the last surviving daughter of the late William Colborne, surgeon, and sister of the late W. H. Colborne, M.D., both of Chippenham, Wilts. aged 79 years.

CRAVEN.—On Nov. 15th, at his residence, 14, Albion-street, Hull, Sir Robert Martin Craven, J.P., F.R.C.S., aged 79 years.

DINGLEY.—On Tuesday, Nov. 17th, at Elm Bank, 277, Camden-road, N., William Dingley, M.R.C S., L.S.A., aged 75 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AUTUMN MANŒUVRES.

To the Editors of THE LANCET.

SIRS,—Permit me to report in THE LANCET one of the most interesting scenes in bird life I have ever witnessed. Doubtless many of your readers are well versed in ornithology and will appreciate the short narrative I venture to give about the handsome and well-known bird the starling. I had read in a local paper that vast numbers of these birds for some evenings past could be seen resorting to a large pond in a park close to Mere, a hamlet between four and five miles from Lincoln, there to drink before roosting for the night in the neighbouring woods. Wishing to see this process I drove over to Mere Hall park on Oct. 22nd and took up a suitable position to observe anything that might take place.

At first I thought my journey would be fruitless but about 4.15 o'clock the birds began to arrive from all points of the compass and in such prodigious numbers that the flocks darkened the sky like thunder clouds and when they alighted on this, their selected place for concentration, their densely packed bodies made fields, hedgerows, and trees black.

As few of the birds drank of the waters of the lake or the stream that runs into it, with a little imagination it might be fancied that the millions of starlings which congregated here were mustered for their autumn manœuvres and not for the purpose of drinking. The birds did not remain long inactive, but began what might be called their evolutions almost immediately and the flocks which were a little late in coming joined in the affair without resting. The host seemed to be formed into divisions—a large central one and a right and left division—each division no doubt having a commander of its own, for the three occasionally acted independently as well as in unison with each other. The Rev. Mr. Wood in his "Natural History" recognises this fact. He says: "In their flight the starlings are most wonderful birds, each flock, no matter how large its dimensions, seeming to be under the command of one single bird and to obey his voice with an instantaneous action which appears little short of a miracle." The various formations of the birds on the wing at Mere were impossible to follow but the central division on one or two occasions performed most beautiful movements. It alighted on some meadows, instantly blackening them, but in a minute or two it arose, the birds on the west flying towards the east and the birds on the east flying towards the west, thus in their flight making a checker pattern and yet in this crowded state there did not seem to be any collisions. The rising of the whole vast host from the ground and the hedgerows was a sight not to be forgotten.

All the units of the great army were in fine plumage and condition. There were numbers of young birds present which were easily recognised by their brownish colour, as starlings do not attain their rich and "glossy varying dyes" until they are three years old. It was a well-disciplined army that knew how to be silent and also when to be musical, but the music was neither sweet nor pleasant for it resembled the sharpening of thousands of saws, the whirring of the wings occasionally mollifying the rasping chatterings.

As the shades of evening closed the flocks began to retire and with a field glass I could see that many of them in retiring executed a variety of evolutions and did not appear anxious to go straight home to rest.

I am, Sirs, yours faithfully,

Lincoln. WILLIAM O'NEILL, M.D. Aberd., &c.

THE CIGARETTE CRAZE.

To the Editors of THE LANCET.

SIRS,—As my letter to you on this subject has brought forth some correspondence I ask your indulgence to enable me to reply to some of your correspondents. First I must thank you for your reply. From it I gather that you consider, and I quite agree, that inhaling the smoke of the cigarette is the cause of most of the ill-effects. When this is done unwittingly the habit, I think, can be overcome by using a long tube preferably, as suggested by the late Sir Morell Mackenzie, with some cotton-wool or other absorbent in it.

I may have expressed myself badly, but your correspondent "E. A. A." is in error if he thinks I intended to suggest that smoking nine or ten cigarettes a day was excessive. On the contrary I said "he did not smoke half an ounce of tobacco a day" (I find that Virginian straight-cuts have an average of 23 to the ounce) and I consider him an average cigarette smoker, and in my opinion he is running as little risk as the average pipe smoker. "E. A. A." implies that if mild tobacco is coarse-cut it will be cool; comparatively speaking, he is right, but I have myself never found a tobacco cool enough for my mucous membrane unless it was too strong for my nerves. Many men, myself included, can smoke cigarettes all day but cannot smoke two pipefuls consecutively. I should be very glad to know where to obtain the tobacco which "E. A. A." uses and which he finds "very mild" and yet is not hot.

From the closing paragraph of Mr. Scanlan's letter I take it that he agrees with me that it is the abuse, not the use, of the cigarette which has caused its condemnation. I have not met any cases such as he mentions—men smoking 300 cigarettes a week. They must have spent almost all their hours awake at it, and although they may not suffer from any disadvantages now I am certain that they will do so in time. The bad effects of alcohol and tobacco are sometimes insidious and some neurologists consider tobacco to be even more injurious than alcohol. I frequently meet men who say: "I am surprised to see you—a doctor—smoking cigarettes," yet they in many cases have a pipe in their mouths all day, and say: "Oh, my doctor says it is healthier than a cigarette"; yet a leading text-book says that tobacco *amblyopia is common in pipe smokers and unknown in cigarette* smokers—*verb sap.*

You have already dealt with the letter of "M. M." I certainly think "bleaching" tobacco must be very uncommon, if adopted at all. I must now thank you for your courtesy. This discussion has left me—in name only,

Sirs, yours faithfully,

Nov. 3rd, 1903. DOUBTFUL.

COOKERY IN THE FRENCH ARMY.

ACCORDING to *Mr. Punch* and other authorities of eminence the average Frenchman is a born cook. In Crimean days stories used to be told how French soldiers could manufacture appetising and more or less *nourishing dishes out of nothing in particular and so kept fat and* well while our poor fellows were next door to starvation. Be this as it may, the excellence of French cookery is proverbial, but if we may credit Lieutenant Billard of the 8th Battalion Chasseurs à Pied the knowledge and skill of the greater part of the cooks in the French army of the present day leave much to be desired. To meet and to cure this great defect he has compiled a manual which has just been published by M. Berger-Levrault of Paris. The work is small in size and easily carried in the pocket, but contains, nevertheless, within the compass of its 40 pages an adequate amount of information. In the first place a series of culinary recipes is given, each recipe being susceptible of preparation under the conditions which prevail in barracks. The instructions are so clear and precise that if intelligently carried out the resulting dishes should not fail to afford satisfaction. Next, menus for a week are set forth *in detail, variety being aimed at as far as possible. This section con*tains also a table or ready reckoner by means of which the quantity of each ingredient required for 100 men can be ascertained at a glance. The whole of the material is then passed in review, the several items being illustrated as well as described. Instructions with regard to the way to tell good articles of food from bad are contained in this section and also sundry useful hints regarding their purchase and conservation. In conclusion, Lieutenant Billard deals with the management of meals. His remarks are distinctly germane, being calculated to promote good fellowship as well as good feeding.

A NEW APPLIANCE FOR PREVENTING ACCIDENTAL POISONING.

PROMPTED by some remarks which appeared in THE LANCET of Oct. 17th and Nov. 7th under "Medicine and the Law" Mr. Haydn Brown has sent to us some specimens of a new patent appliance for preventing accidental poisoning. It consists of a flat tin disc having the word "Poison" stamped on it, which can be fitted on to the neck of a bottle like a collar, although the eight points made by a corresponding number of scallops in the outer edge of the disc give it more the appearance of a frill. "It is instantly fixed," says the inventor, "by pulling the free ends apart at right angles to the plane and passing it round the neck. It is not easily removed again by those who do not know how. If the persons handling the poison bottle do not prick the fingers at first they are almost certain to do so on replacing the cork or putting the [illegible] one. We presume the discs would have to be made in different sizes to fit different sizes of bottles and it appears to be necessary that the bottle should have a prominent rim at the mouth to prevent the disc from falling off when the bottle is inverted.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—As a driver of a car in London for nearly three and a half years perhaps a few details may be of service to your readers. The car was a De Dion voiturette, three and a half horse-power. The distance travelled was from 18 000 to 19,000 miles. The cost per annum was *about £130 (as against £200 for single horse and carriage).*

	£	s.	d.
Tyres, pneumatic	25	0	0
Petrol	20	0	0
Lubricating oil	2	0	0
Repairs	20	0	0
Sundries	5	0	0
Taxes and insurance	10	0	0
Boy at 16*s.*	41	0	0
Rent of stable	15	0	0

I am quite satisfied with the change and do not think I would, in any circumstances whatever, again keep a horse. Only on six occasions have I been stopped on the road by small troubles which I could not immediately rectify myself and two of these were at the end of *journeys of over 100 miles.* I am my own mechanic. In my opinion a motor car is far preferable to a horse and carriage for general practice as it does not tire and mine is always at my command whenever needed night or day. My stable is a minute's walk from my house. I can have my car upon the road without assistance *in three minutes from the time I leave my door.*

The points for consideration in the choice of a car by a medical man vary according to the depth of his pocket. If he be content with a light open voiturette, under ten hundredweights, run upon pneumatic tyres (or solid) and will look after the mechanical parts himself, keeping a lad simply to wash and to oil the car the expense need not be *greater than in my case. But if, on the other hand, he chooses a car* weighing from 15 to 30 hundredweights he would, if a busy man, be compelled to keep a mechanic If he has pneumatic tyres and uses his car as much as I use mine he will find his cost of running comparatively heavy—his tyre bill alone may be anything between £100 and £300 per annum. Not only are pneumatic tyres expensive but to find one's tyre deflated by a puncture just when one has an urgent message is more than annoying. I have had only one puncture (in August, 1903) since January, 1901. My little car is to-day in perfect condition throughout—it is in far better order than when I first bought it nearly new. It is, of course, only a motor-perambulator as cars go nowadays, but I have averaged 15 miles per hour from Birmingham to my house (running time), "three up" and a large portmanteau on board. I have done a mile in two and a half minutes. It will climb any ordinary hill. I have driven it up the West Hill, Highgate, and Aubrey-place, Holland-hill, W. It has twice refused to take me up Netherhall-gardens, it went up empty. When buying a car the medical man should buy one with a good family history, unless he proposes to experiment. If I were going to buy a car now I should certainly get a six horse-power De Dion voiturette.

I am, Sirs yours faithfully,

G. WASHINGTON ISAAC, M.B. Edin.

Gower-street, W.C., Nov. 9th, 1903.

To the Editors of THE LANCET.

SIRS,—In answer to "Tramite Recta" in THE LANCET of Nov. 7th allow me to say that though a motorist and a medical man I would *advise him not to expect too much from motor-cars, for none can climb* a hill of 1 in 3; secondly, not to use pneumatic tyres; thirdly, to get a light car of the Baby Peugeot type, price about £160 or so, with solid tyres and seats for two; also he should not get a car for hilly country to carry four passengers unless he has adequate (from eight to nine) horse-power; lastly, unless he is prepared to understand his machine thoroughly and to carry out small repairs himself "Tramite Recta" will regret ever buying a motor-car. As to tyres, if he does not have ordinary clincher tyres he should have Connolly's Goodrich or Hearthstone (not the ideal or wired on) tyres.

I am, Sirs, yours faithfully,

Nov. 9th, 1903. J. C., M.D.

PS.—As a rule the small American cars and those driven by steam should be avoided.

To the Editors of THE LANCET.

SIRS,—We notice under the heading of "Motor-cars for Medical Men" in THE LANCET of Nov. 7th, p 1337, a letter, over the signature of "Tramite Recta," asking for information respecting a light car. It may be of interest to your correspondent to know that we have supplied several of our smaller cars—namely, five horse-power and seven and a half horse power—to medical men for use in their practice and have *received excellent reports regarding their suitability for this* class of work. We shall be pleased to send you the names of medical men to whom we have supplied cars in order that you may put your correspondent in communication with them.

We are, Sirs, yours faithfully,

WOLSELEY TOOL AND MOTOR CAR COMPANY, LTD.

(H. AUSTIN, Manager.)

Birmingham, Nov. 10th, 1903.

To the Editors of THE LANCET.

SIRS,—I have noted with interest the remarks in the recent numbers of THE LANCET about motor-cars. As perhaps you may call to mind, I had the pleasure of giving my experiences some time ago; probably my subsequent ones may interest medical embryo motorists.

I fully agree with Mr. H. Lupton that many motors are useless to medical men and that no car which runs on pneumatic tyres is (to medical men) worth having Personally I have always used solid tyres and found them to wear well. I have had two cars, both Benz make—the latter a four and a half horse-power horizontal single cylinder, belt transmiss[illegible] *These manufacturers* have now [illegible] ical. I ordered some three week[illegible] om Brown Brothers, Great Eastern street, E., the specifications of which are as follows: two cylinders, eight horse-power, clutch transmission, chain driven, positive feed, mechanical lubricator, three speeds forward and reverse operated by one lever artillery wheels fitted with two-and a-half inch [illegible] with side [illegible] water-[illegible] all the other makes on the market. Its power, build, and simplicity influenced my decision and especially its performance on a trial trip here up a winding hill of 1 in 4. I trust in six months to be able to report well as to its behaviour.

I am, Sirs, yours faithfully,

Woolwich, Nov. 7th, 1903. CHARLES T. W. HIRSCH.

THE EMPLOYMENT OF RESERVE AND DISCHARGED SOLDIERS.

Lieutenant-General Green-Wilkinson, chairman of the National Association for the Employment of Reserve and Discharged Soldiers, writes to us pointing out that men who have served in the army deserve well of their country and appealing to employers of labour, especially county and borough councils, to continue to show their sympathy. He gratefully acknowledges that much has been done by employers in this respect, for after the close of the late war, of 24,000 men registered, 18,000 have been given permanent work. Recently, however, applications for men have been fewer and the candidates for registration are increasing owing to the present service of three years with the colours instead of seven years as heretofore. Openings are required for coachmen, grooms, carmen, timekeepers, porters, labourers, and others. The offices of the association are at 119, Victoria-street, London, S.W. The telephone address is "367 Westminster" and the telegraphic address is "*Employons, London.*"

THE RÔLE OF SOAP.

To the Editors of THE LANCET.

SIRS,—For many years past I have been interested in a personal degree as to "the rôle of soap" on the human skin and have come to the following conclusions. Skins vary according to the constitutions of individuals. Those having an oily skin (chiefly persons of dark type) are more satisfactorily washed by using a certain amount of free alkali in its constitution; on the other hand, the possessors of dry skins (mostly fair-complexioned persons) cannot stand the effect of free alkali and in such subjects a superfatted soap not only removes the dirt but leaves a trace of fat on the surface, thus counteracting the drying and cracking effect of the more alkaline soap. A rough-and-ready mode of testing one of the pure superfatted soaps is to wash the mouth and teeth with it, using a soft brush and warm water.

I am, Sirs, yours faithfully,

Nov. 14th, 1903. H. J C.

THE BRITISH MEDICAL BENEVOLENT FUND.

THE following is a third list of donations received in response to Sir William Broadbent's appeal:—

	£	*s.*	*d.*		£	*s.*	*d.*
Dr. P. H. Pye-Smith, F.R.S.	10	10	0	Mr. B. G. A. Moynihan	2	2	0
Dr. W. S. A. Griffith ...	10	0	0	Mr. S. Evans	2	2	0
				Mr. C. J. Denny	1	1	0

The treasurer is grateful for the response already given to Sir William Broadbent's appeal. Unfortunately the amount of money received still falls far short of the requirements of the fund at the present time and unless the resources of the fund are largely increased the pressing claims which winter always brings will be very inadequately provided for. Further subscriptions and donations are urgently needed and may be sent to the treasurer, Dr. S. West, 15, Wimpole-street, London, W.

THE CHOICE OF A SPHYGMOGRAPH.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent *re* sphygmograph, I can with confidence recommend Dudgeon's. I have used this instrument in my general practice in all cases of cardiac disease and many others for over 20 years. It has always worked well and never gone out of order. It costs £2 5s. and when care is taken in the selection of the proper paper I think it the best for every-day use.

I am, Sirs, yours faithfully,

Crieff, N.B., Nov. 15th, 1903. D. ROBERTSON DOBIE.

MANUSCRIPTS OF MEDIÆVAL MEDICAL AUTHORS.

Dr. George A. Kostomoiros of Athens, whose valuable researches upon the unedited manuscripts of Greek and Latin medical writers were reviewed in THE LANCET of March 30th, 1895, p. 822, has recently followed up his account of the texts of the more ancient authors by some notes upon three writers of the mediæval period whose books are of importance, not so much for their own researches and compositions, as for the extracts which they made from far older and more valuable medical literature. These three writers—Joannes Tzetzes, Nicolas Myrepsus, and Joannes Actuarius—lived in the twelfth and thirteenth centuries of the present era. The first, who was at once a poet, a grammarian, and an encyclopædic writer, was born in 1110. He included medicine among the many branches of his erudition and there is at Oxford in the Codex Baroccianus, No 88, a little treatise composed by him upon the Urine. Nicolas Myrepsus, of Alexandria, was the writer of a complete "Dynameron" in which between the years 1277-80 he collected all the best recipes he could find in Arabic and Greek treatises, forming a complete pharmacopœia as the subject was then understood. There are 15 manuscripts of it known to exist in Europe; one of them is at Oxford (Baroccianus CLXXI. of the teenth century) and is cursorily described in Daremberg's "Notices et Extraits des Manuscrits Médicaux" published at Paris in 1853.

England unfortunately no longer possesses two of her finest manuscripts of Joannes Actuarius, which were in the library of Sir homas Phillips and are now at Berlin. They contained the Therapeutica and the treatise on the urine. There are, however, at Oxford two others of value and one late and defective codex. In London there are others giving the first and second books of the Therapeutica, two of its unpublished books, and also two codices of the treatise on the urine. It is to be hoped that Dr. Kostomoiros will soon publish further results. Joannes Actuarius wrote about 1250. The number of his known works is five or six, the most important of which are the treatise on the urine, in seven books (see Ideler: "Physici et Medici Græci Minores," II.; 193, Berlin, 1841), and the Therapeutica, in six books prepared for the use of Apokaukos, Chamberlain at the Byzantine Court. Of the latter two books only have been published in Greek by Ideler.

A CHEAP OPEN-AIR SANATORIUM.

"W. E. F. T." asks us to publish a request to our readers for information concerning a cheap open-air sanatorium.

◆

Sufferer.—We do not recommend treatment, but the condition is a very common one upon which any medical man can give sound advice. Our correspondent is especially warned against having recourse to the many mischievous quacks who offer cures. Cure will certainly follow upon the rigid cultivation of habits of self-control, and there is no need for the despondency expressed.

M. P. H. has omitted his name and address. The Medical Directory will give him the information that he seeks.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

TUESDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.).

WEDNESDAY (25th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.) Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M).

THURSDAY (26th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat, (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

FRIDAY (27[illegible] [illegible] lomew's (1.30 P.M.), St. Thomas's [illegible] Cross (3 P[illegible] (2 P.M.), [illegible] Northern Central (2.30 P.M.), West London [illegible] 2.30 P.M.), Throat Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.).

SATURDAY (28th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (23rd).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (2 Hanover-square, W.).—7 P.M. Council. 8 P.M. Annual Report and Balance Sheet. Papers:—Mr. W. S. Nowell: A Case of Bilateral and Partial Necrosis of the Mandible.—Dr. H. Tilley: Some Observations upon Empyema of the Maxillary Antrum, with Special Reference to the Diagnosis and Treatment. (The paper will be illustrated by Diagrams, &c. The method of "Transillumination" and "Intranasal Exploration" for diagnostic purposes will be demonstrated upon a patient.)

MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper:—Sir R Douglas Powell, Bart: The Action of Medicinal and other Remedies in Cardiac Failure.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (St. Mary's Hospital).—4 P.M. Annual General Meeting. Election of Officers. Papers:—Mr. F. G. Parsons, Dr. W. Kidd, Dr. A. Keith, Dr. W. [illegible]

[illegible] OCIETY (Apothecaries' Hall, [illegible] ting. 4 P.M. Papers:—Prof. [illegible] id their Alkaloids.—Dr. R. B. [illegible] to the Pharmacology of the Saponins.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper: Mr. T. Crisp English: Remarks on Fifty Consecutive Cases of Perforated Gastric and Duodenal Ulcer treated by Laparotomy.

WEDNESDAY (25th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Pathological Evening. Exhibition of Specimens.

FRIDAY (27th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. F. C. Wallis: A Case of Chronic Intussusception treated by Intestinal Resections (to be illustrated by the epidiascope).—Dr. F. Taylor: Two Cases of Lymphocythæmia (Lymphatic Leukæmia).—Mr. L. McGavin: A Case of Post-operative Hernia treated by the Introduction of Silver Wire Filigree.—Dr. N. Dalton: A Case of Malignant Anæmia.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are *payable in advance. Cheques and Post Office Orders* (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

A Lecture

ON

THE ADMINISTRATION OF CHLOROFORM TO MAN AND TO THE HIGHER ANIMALS.

Delivered in the Physiological Laboratory of the University of London on Oct. 13th, 1903.

BY AUGUSTUS D. WALLER, M.D., F.R.S.

GENTLEMEN,—On previous occasions, when it has fallen to my lot to replace one of my colleagues in this lecture-room, I have invited you to inspect the work that happened to be in progress in the laboratory, and to the best of my ability I have explained the origin, the state, and the purpose of what you have seen. I shall again employ my lecturer's hour in this way, and lay before you as fully as possible in the time the state of the case concerning the experimental study of anæsthetics, which, as some of you know, has been a principal subject of study in this laboratory during the past year. And whereas last summer I dealt at length with purely scientific aspects of the problem, I shall to-day confine myself to the practical side, which is the direct logical consequence of the scientific side—that is to say, that I shall deal with the administration of chloroform to man and to the higher animals.

Some preface is, however, necessary. Although these lectures are addressed to students of second degree possessing already such primary information as may be acquired in the regular medical curriculum, it has happened that non-medical persons, unacquainted with the first rudiments of medical study, have obtained permission to be present. To anyone who has attended the lectures and practice of the laboratory during the past year it will, I hope, be matter of surprise that two intelligent young ladies should have come here for many days and have neither seen nor learned anything to give them pause from rushing into print with a horrified condemnation of physiology and of physiologists. If the two young ladies under whose name the publication entitled "Shambles of Science" has appeared, came simply to get "copy" the case is easily understood; but I am unwilling to believe this; and, indeed, the case looks to me much more like that of a pair of very ill-advised busybodies supporting each other through a trying ordeal for the sake of what they imagined to be an errand of mercy. I am sorry they came. I should have told them or any other non-professional women that they had better not come to such lectures, for they would run the risk of being misled and pained by experiments where no suffering to living animals was caused. Indeed, one would look very much askance at the young woman who should be able to look on while an animal was, as she imagined, undergoing torture.

For the naked details of even a properly conducted vivisection, ignorantly considered, as must be the case if they are considered at all by an unprofessional person, appear revolting—so do the details of a surgical operation or of the slaughter of an animal for food, or of the proceedings in the dissecting-room and the post mortem room. The minute and graphic account of such details by ignorant women is from every point of view mischievous and deplorable, and I very much regret that these two unfortunate ladies should have obtained the opportunity to torment themselves and their readers by their conscientious misrepresentations. Physiologists, when vivisection is necessary, do not take either pleasure or pain in its naked details, and they systematically take due precautions to fully anæsthetise animals required for experiment. The incredible motives sometimes attributed to physiologists by well-meaning people and the unlimited adjectives and substantives by which they are held up to public reprobation can only be left to the antidote of their own excess. It is really labour lost to be constantly pleading "not guilty" to this, that, or the other quite outrageous statement; we can only wonder that well-meaning people can so quietly harbour such infamous thoughts.

Nor have we failed to question our own conscience. We well know that physiologists are subject to the common laws governing the human mind and that habit must tend to engender inattention and that inattention would be cruelty. We are on our guard against our own inattention, but knowing that we are human we do not resent as indignantly as might be expected of us the reminder to be on our guard that is contained in the denunciations of our critics. We also know that there is evil in the appearance of evil, that things right and proper in themselves but offensive of appearance ought not to be exposed. And if exposure by even competent authority must offend and injure the imaginations of ordinary men and women, how much more injury and offence to the public mind will be committed by incompetent and self-deluded women who have entered what is to their minds nothing more than a chamber of horrors, where in reality the "quivering flesh" and "palpitating heart" and "tortured nerves" are more often than not only the living parts of dead animals, and where in any case an animal, even if alive, has been absolutely deprived of sensation. When one attempts to realise what kind of images must hold possession of an ignorant, prejudiced, and sensitive person—man or woman—who has seen without understanding, he ceases to wonder at bad language, yet what can he hope to say that shall reach the mind of the deluded fanatics whose pity has been fanned to hatred by agitators. And can it be expected of us that we should say anything at all to persons who can employ sensational literature to poison the wells of human sympathy.

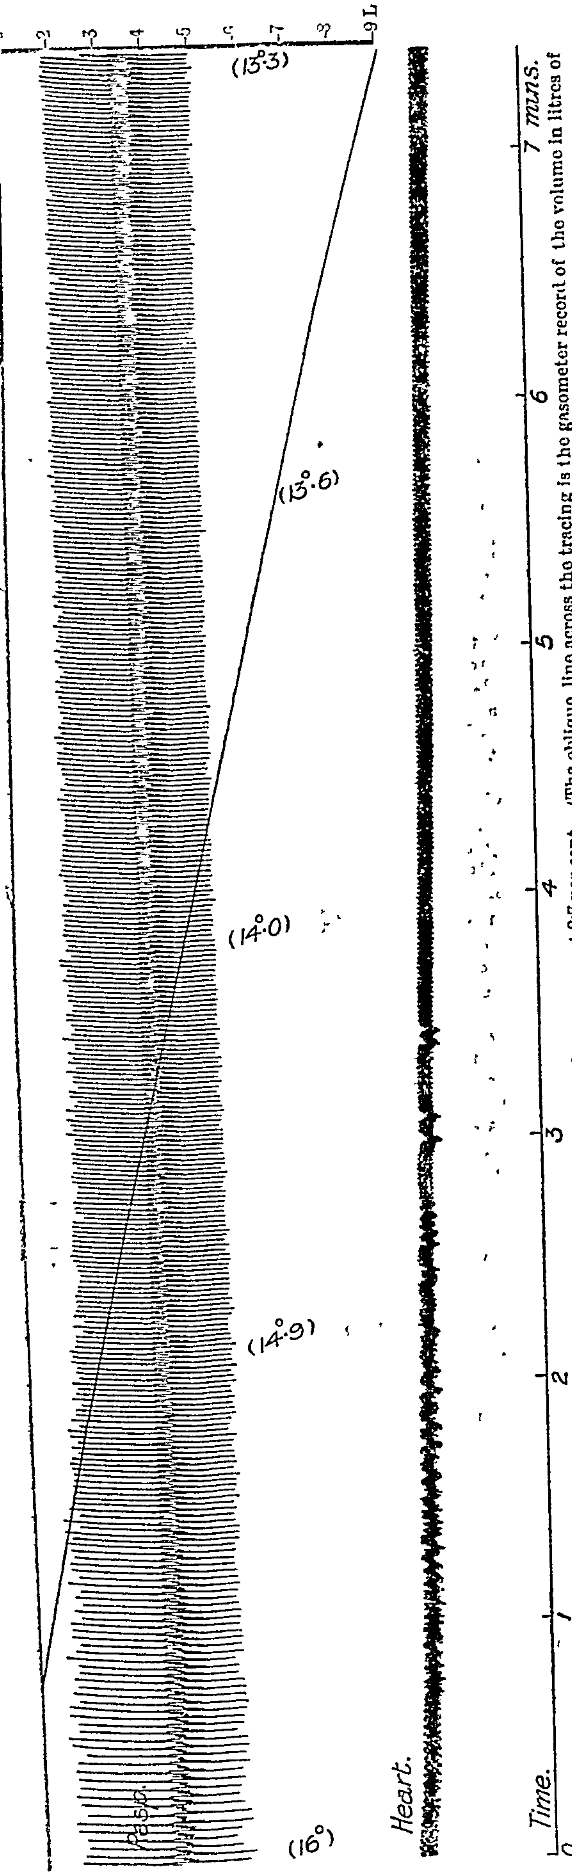
In this laboratory—and no doubt in others—our very first concern is to administer anæsthetics properly when anæsthetics are required. And I make the deliberate statement that animals in this laboratory are anæsthetised with as great certainty and accuracy as are the patients in any hospital in the United Kingdom. Can it be necessary to tell you that we do not juggle with bottles of "colourless and odourless" liquid as imagined and stated by the two ladies who have visited these "shambles"? You shall see for yourselves what takes place outside the lecture-room whenever it is necessary to anæsthetise an animal. I have chosen cats for my demonstration, since the demeanour of these animals is most familiar to us.

Cat No. 1 was anæsthetised three hours ago by the inhalation of chloroform and air at 2 per cent. and has during the last three hours been maintained in profound anæsthesia in a mixture of between 1 and 1 5 per cent. I now pass it round the class, so that you may all assure yourselves of its state, and when it returns to the lecture table it will be left to recover. Its recovery will take place in not less than half an hour nor more than three-quarters of an hour, and will, I believe, be complete within an hour. By complete recovery I mean that state in which the cat will drink milk and purr, and a saucer of milk is therefore placed by the cat as its normal test. You will have understood from this illustration that complete anæsthesia can be, and regularly is, established as long as necessary for the purpose of experiment; and you will hardly need to be told that the anæsthesia can be kept up by a continuous administration, or strengthened if it should at any moment appear to be weakening.

On Cat No. 2 you will see how anæsthesia is induced, and Cat No. 3, which has been left upon the operation table for another purpose, will serve to let you see how the anæsthesia has been maintained throughout an operation. Cat No. 2 has been borrowed for the purpose of this lecture on the understanding that it shall be returned intact. It is to be fully anæsthetised by a mixture of chloroform and air at 2 per cent. according to the regular custom of the laboratory. The induction of complete anæsthesia will take not less than five minutes nor more than ten minutes, and the recovery will be complete in half an hour. I shall also show you how we verify that the mixture is at or about 2 per cent., and in so doing I shall have demonstrated to you how we ascertain the percentage of any unknown mixture of chloroform and air.

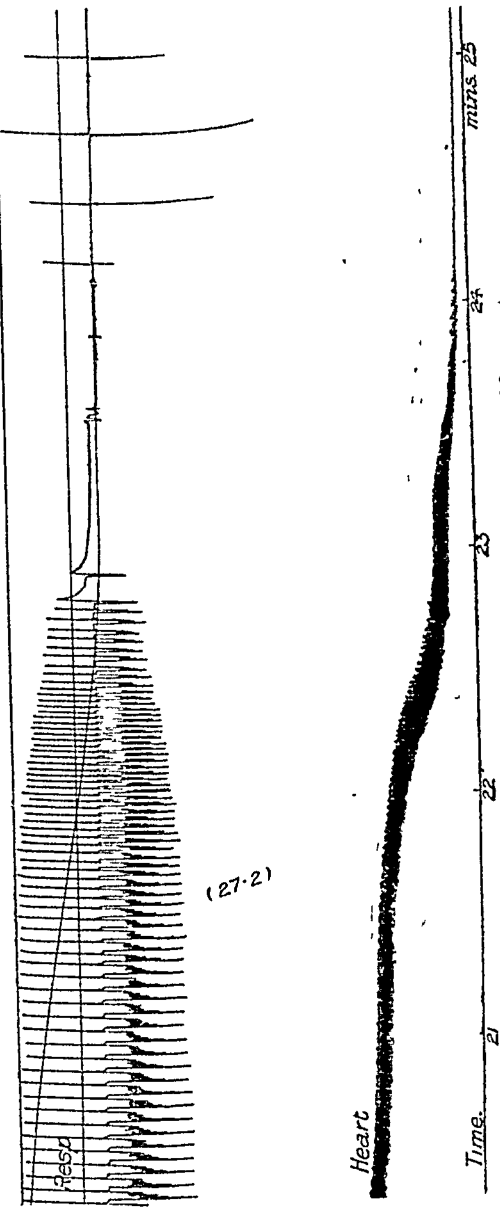
Cat No. 3, now upon the operation board, is dead, having just served for an experiment in which we measured the amounts of chloroform inspired and expired (1) during a normal induction of anæsthesia by chloroform at a low percentage and (2) during a normal production of death by chloroform at a high percentage. Throughout this experiment we have observed and recorded the respiration and the blood pressure, the percentage of chloroform in the inspired and expired air, and the total volume of air breathed per minute

The results of the experiment are contained in the record now on the cylinder (Figs. 1 and 1A) and in the numbers



Experiment of Oct. 13th, 1903 (Part 1). Cat weighing 2 9 kilos. Anæsthesia by chloroform vapour at 2·7 per cent. (The oblique line across the tracing is the gasometer record of the volume in litres of air breathed by the animal. The numbers in brackets signify the temperature of the chloroform.)

FIG. 1A.



Experiment of Oct. 13th (Part 2). Death by chloroform at 14 2 per cent

written on the blackboard (*vide infra*). The remainder of my lecture will be occupied by an explanation of the exact manner in which these several observations have been carried out, and by a very few concluding remarks concerning the anæsthesia of the human subject.

Experiment made on Oct. 13th on a Cat weighing 2·9 kilos.

Part I.—Induction of complete anæsthesia by nine litres of chloroform and air at 2·7 per cent. $CHCl_3$ in 7 minutes 40 seconds. The frequency of respiration was 70 per minute with an average depth of 16 cubic centimetres per respiration.

Inspired ...	2 7 per cent.,	i.e.,	243 cubic centimetres of $CHCl_3$ vapour in 9 litres of air.	
Expired ...	2·1	,,	189 cubic centimetres.	
Retained ...	0·6	,,	54 ,, ,,	(or 0 27 gramme).

Part II.—Death by two litres of chloroform and air at 14·2 per cent. in three minutes.

Inspired ...	14·2 per cent.,	i.e.,	284 cubic centimetres of $CHCl_3$ vapour in 2 litres of air.	
Expired ...	7·9	,,	158 cubic centimetres.	
Retained ...	6·3	,,	126 ,, ,,	(or 0·63 gramme).

Of course, such an estimate of the total quantity of chloroform absorbed during a given period would be more immediately satisfactory if that total quantity could be directly measured. But I have ground for concluding that the result obtained by calculation from the percentage of given samples and the total volume of air used, does actually represent a close approximation to such total quantity In a series of trials made last year of the delivery by an apparatus recently proposed for clinical anæsthesia I measured (1) the total volume of air drawn over a weighed amount of chloroform, (2) the loss of weight of the chloroform, and (3) the percentage of chloroform in the issuing air by densimetry The percentage as given by the densimeter sample is very nearly that afforded by the quotient of total air divided by total chloroform —

1 Total of air in litres	2 Loss of $CHCl_3$	Percentage calculated from (1) and (2)	3 Percentage by densimetry
25 2	2 38 (476 c c)	1 89	1 90
12 6	1 56 (312 c c)	2 48	2 30
8 4	1 29 (258 c c)	3 07	3 10

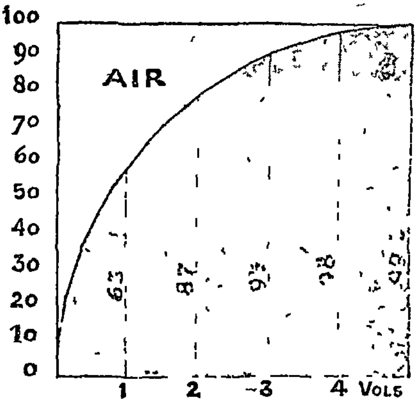
All three cats have gone through the proceeding you witnessed in the case of the borrowed cat—it is our regular laboratory procedure for cats dogs, rabbits, rats, mice pigeons and frogs—and the differences of susceptibility to chloroform exhibited by these various animals are so small that we are justified in translating to the human subject the knowledge we have acquired at their expense The animal is placed under a glass bell jar through which chloroform and air of known percentage are pumped The pump is one originally devised by Professor R Dubois of Lyons for the *anæsthetisation of the human subject and has proved very* valuable as a laboratory instrument The only objection to its use is, as far as I can ascertain, its price—£20, but as a matter of fact as a laboratory instrument it is commercially economical We have never lost an animal by chloroform since it has been in use, and the amount of chloroform employed in the laboratory has been comparatively small, the certainty and safety with which anæsthesia has been induced have very materially lightened the preparations for an experiment, it has enabled us to keep animals in complete anæsthesia for as long as 12 hours

At each stroke of the pump four and a half litres of air are delivered at the outlet and an equal amount is drawn in at the inlet The inlet is by an open bottle into which each stroke automatically delivers 0 3 cubic centimetre (five minims) of liquid chloroform, equivalent to 90 cubic centimetres of chloroform vapour, the whole of which is drawn into the pump at one stroke and delivered at the next stroke Thus at one, two three or four strokes per minute the delivery is 4 5, 9 13 5 and 18 litres per minute of a 2 per cent mixture of chloroform and air, and whether the pump is worked quickly or slowly (within reasonable limits) the percentage remains at this figure, which is the maximum value afforded in the automatic working of the apparatus (but can be lowered to 1 6 and 1 2 per cent by turning a cam or raised to between 3 and 4 per cent if demanded)

The nominal delivery of this (or of any other apparatus) is readily tested by the densimetric method [1] A 250 cubic centimetre bulb, previously counterpoised on a balance, is placed upon the delivery tube, filled with the mixture closed, and replaced upon the balance It is found in the case now before us that an addition of 22 milligrammes is required to the counterpoise—i e, that the percentage of chloroform in the sample is 2 2. The data upon which this method of estimation is based are as follows Each cubic centimetre of chloroform vapour is four milligrammes heavier than one cubic centimetre of air, so that 2 5 cubic centimetres—i.e, 1 per cent in the 250 cubic centimetres flask—are ten milligrammes heavier Ten milligrammes signify, therefore, 1 per cent and 22 milligrammes 2 2 per cent.

It will be worth while to realise the way in which the percentage of chloroform in a reservoir rises to that of a chloroform plus air mixture delivered through it. Fig 2 will help you to do so You may see from it that a reservoir through which once, twice, thrice its own volume of a mixture has been slowly passed, contains a more dilute mixture at 0 63 0 87 0 95 of the percentage of the original mixture, and that when five times the volume has passed, the *percentage in the reservoir is practically equal to that of the* supply For a bell jar of 30 litres supplied by a chloroform mixture at 2 per cent at a rate of 30 litres per minute (seven strokes per minute of the Dubois's pump are more than sufficient for this) the percentage in the jar at the end of the one, two three, four, and five minutes will be 1 26 1 74 1 90 1 99, and 1 99 And as regards the densimeter bulb by which we just sampled the percentage of supply, a single stroke driving ten times its volume of gas through the bulb is obviously more than sufficient to give a full strength sample of mixture in the bulb

FIG 2



To illustrate the rate at which the air of a receiver is replaced *by chloroform mixture of any given strength When the* receiver has been traversed by once twice three times &c, its volume of mixture the contents = 63 mixture + 37 air 87 mixture + 13 air &c The mixture is practically at its full strength when the receiver has been traversed by five times its volume

Let us turn our attention to the results obtained on Cat No 3 It was first anæsthetised under the bell jar, a cannula was then placed in the trachea connected by a tube with a Woulfe s flask containing chloroform so that the inspired air was charged with an unknown amount of chloroform vapour by which the anæsthesia was maintained. This is the ordinary laboratory method of keeping up anæsthesia but it is a dangerous method and one that is not used in this laboratory except for the actual study of chloroform, we prefer ether for ordinary use In the present case, the purpose of the experiment being to get at the percentage and amount of chloroform administered, a densimeter bulb is placed on the inspiration tube and the total amount of air inspired is measured by a gasometer In the present case the total amount of air inspired was nine litres (in seven minutes 40 seconds) and the percentage of chloroform vapour in that air was 2 7 The total volume of chloroform vapour taken into the lungs was therefore 243 cubic centimetres, or rather more than one gramme of fluid chloroform

Was all this chloroform vapour retained? Probably not, or rather evidently not since the expired air of the animal smelt strongly of *chloroform How much then was the* amount of chloroform rejected in the expired air? To *ascertain this* was a *rather more troublesome matter*, a Chauveau s valve (Fig 3) connected with two densimeters, one on the inspiratory and the other on the expiratory side, was ultimately found to answer the purpose extremely well The flaps of the valve act perfectly with inspirations and expirations ranging from 10 to 1000 cubic centimetres and the "dead space of the apparatus is as small as possible so that the column of air moved to and fro with respiration is not much greater than that of the large air passages We have to prevent any condensation of water vapour from taking place in the expiration bulb To this end it is placed in a metal chamber kept at between 40° and 50° C by an incandescent lamp and to *keep things equal* the inspiration bulb is placed by its side in the warm chamber A slight increase of weight (1 3 milligrammes per 1 per cent) in the expiration bulb by reason of the CO_2 expired is either allowed for or estimated separately Its accurate determination might be of importance in low percentage estimates; but in high percentage estimates, like the present the error due to this source may be disregarded. Thus 5 per cent. of chloroform is signified by 50 milligrammes and 4 per cent. of CO_2 is signified by 5·2 milligrammes; for ordinary purposes then it is well to subtract five milligrammes from the weight of the expiration bulb as the average value of the CO_2 weight in expired air.[2]

---

[1] Proceedings of the Physiological Society, 1903

FIG 3.

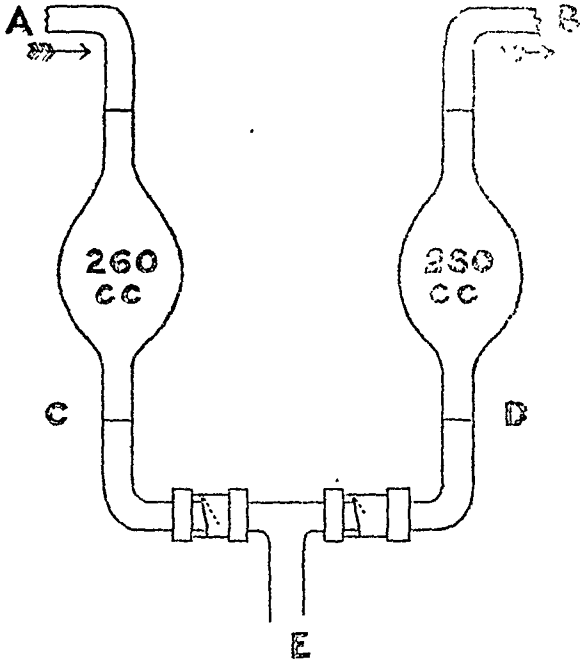


Diagram to show the arrangement of apparatus for the estimation of chloroform in the inspired and expired air. Tube A is attached to a chloroform flask, tube B to a gasometer. Tube E of the Chauveau valve is connected with the trachea. Two densimeters are attached to its inspiratory end C and to its expiratory end D. (The warm jacket enclosing the densimeters is not shown.)

We are now in a position to draw up a more complete balance-sheet showing the pulmonary absorption of chloroform during a given period, the excess of income over output representing what has been retained in the body during that period. In the case before us the percentage of chloroform in the expiration densimeter was 2 1, or 189 cubic centimetres of chloroform vapour were rejected in the nine litres of expired air. So that we have :—

Chloroform inspired	...	243	cubic centimetres.		
,, rejected	...	189	,,	,,	
,, retained	...	54	,,	,,	(= 0·27 gramme).

That has been the story of the induction of profound normal anæsthesia by chloroform vapour at a rather high, but not in itself a dangerous, percentage. The amount of chloroform rejected was greater (and of that retained was smaller) than I have seen in other similar experiments. I attribute this to the character of the breathing which was rapid and shallow—above 60 per minute.

Turn now to the second part of the experiment, when the cat was deliberately sacrificed by the inhalation of chloroform at a high percentage, all arrangements being made as before to record the movements of respiration and the blood pressure, the percentage of chloroform in the inspired and in the expired air, and the total volume of air breathed. Death occurred, as in the great majority of such cases, by failure of respiration, followed by failure of the heart The percentage of chloroform as given by the inspiration densimeter was 14 2, by the expiration densimeter 7·9 (corrected for 2 per cent of CO_2 determined volumetrically). The total volume of air breathed was two litres in three minutes, when respiration ceased. We have in this normal death by chloroform at a high percentage the following result.

Chloroform inspired	...	284	cubic centimetres.		
,, rejected	...	158	,,	,,	
,, retained	...	126	,,	,,	(= 0·63 gramme).

Commentary is hardly necessary; the facts speak for themselves. In Part I. an animal was fully anæsthetised by chloroform absorbed at the rate of 27 milligrammes per minute. In Part II the same animal was killed by chloroform absorbed at the rate of 210 milligrammes per minute.

For the sake of comparison with the results of to-day's experiment I have set out for your inspection the principal data of a similar experiment made two days ago on a dog.

Experiment made on Oct. 11th on a Dog weighing Seven Kilogrammes.

Part I.—Induction of complete anæsthesia by 8·5 litres of chloroform and air at 3·1 per cent. of $CHCl_3$ in four minutes 30 seconds.

Inspired ...	3·10	per cent.	......	263·5	cubic centimetres.	
Expired ...	1·86	,,	......	158·1	,, ,,	
Retained ...	1·24	,,		105 4	,, ,,	(= 0 527 gramme).

Part II.—Death by eight litres of chloroform and air at 13·2 per cent. $CHCl_3$ in three minutes.

Inspired ...	13 2	per cent.	......	1056	cubic centimetres.	
Expired ...	6 66	,,	......	533	,, ,,	
Retained ...	6·54	,,		523	,, ,,	(= 2 615 grammes).

One accident, and one only, has occurred in this laboratory since the procedure which you have just witnessed has been regularly adopted. It was not due to the procedure but to its absence. The accident was so strikingly instructive that I shall give you an exact account of how it occurred and of what we learned from it. The animal—a cat—had been fully anæsthetised and transferred to the operating table when the operator was called to some other more urgent matter. On his return he found the animal undergoing artificial respiration which failed to restore it. Death had taken place. The animal had shown signs of recovery from the anæsthetic and had been re-anæsthetised by "*a few drops of chloroform on a cloth*" which had caused sudden arrest of the heart and of respiration. The accident was obviously a case of early cardiac death of the kind well known to physiologists and dreaded by surgeons. I believe that it can only occur when a sudden wave of concentrated chloroform vapour reaches the lungs and pulmonary blood, and I adopted the following device to ascertain whether the conditions under which the accident had just taken place were compatible with the reason given.

An open glass tube was placed between the teeth of the dead animal and connected with a densimeter bulb and an aspirator that drew two litres of air through the bulb in two minutes. A few drops of chloroform were poured on a cloth which was wrapped round the head of the animal as previously for the production of anæsthesia. The percentage of chloroform found in the air aspirated through the densimeter was found to be 11·2. A second trial with the cloth more loosely applied gave the percentage 2·5 A third experiment with the cloth held away from the head of the

FIG. 4.

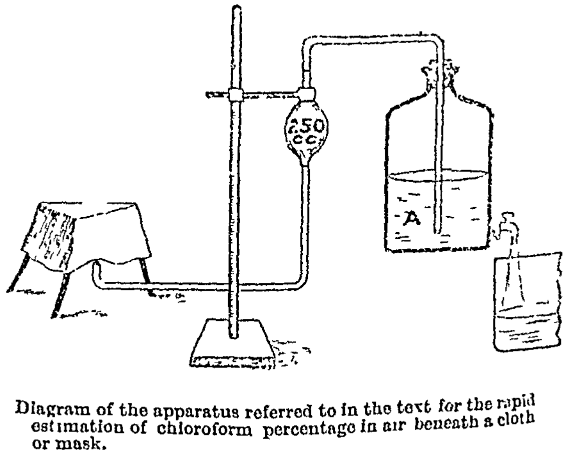

Diagram of the apparatus referred to in the text for the rapid estimation of chloroform percentage in air beneath a cloth or mask.

---

[2] A respiratory quotient of 0 9 has been assumed in the calculation of the densimetric value of CO_2 in expired air.

animal gave the percentage 1·2. The tube was then removed from the animal and clamped under a tripod on which the cloth was placed. Chloroform was then put on the upper surface of the cloth drop by drop and the aspirator A was set going for two minutes so as to draw two litres of air *plus* chloroform vapour. The sketch (Fig. 4) will show you exactly how the cloth, the tube, the densimeter, and the aspirator were disposed. The distance between the cloth and the mouth of the tube was three inches, the temperature of the room was 18·5° C. (65·3° F.), and the barometer stood at 768 millimetres of mercury. The percentage by the densimeter was 0·8. In subsequent trials the percentage was 0 7, 1·0, 0 8 with the cloth loose over the tripod, and 1 9 with the cloth more closely wrapped round it. I now understand as I never understood before how it is that an "open method" *involving the administration of "plenty of chloroform with plenty of air" is a relatively safe method.* It is relatively safe because under the ordinary physical conditions of the method, with due skill and unflagging watchfulness on the part of the administrator, the amount of chloroform vapour in the mixture of chloroform and air offered to inspiration is as a rule between the desirable limits of 1 and 2 per cent. It must be obvious to you that this simple apparatus places in your hands the means of studying the kind of chloroform percentage offered to the inspiration of a patient by any of the various masks and other apparatus that are in use for the chloroformisation of the human subject.

The relative danger of a closely fitting mask, even when the *chloroform is given drop by drop, cannot but be evident* to you. The reason of the relative safety of the Edinburgh practice—plenty of *chloroform with plenty of air*—will be no less intelligible. Lawrie, the most convinced and persistent advocate of this method, gives "doses" of chloroform that are enormous, but he is careful that the amount he uses shall not reach the patient's lungs. There is no special virtue in any mask; one towel is not more dangerous than another, nor is there any good reason why it should be *preferred to a piece of lint. That method is safest* which best secures that the patient shall continuously inspire a mixture of chloroform and air with not less than 1 per cent. and not more than 2 per cent. of chloroform vapour in the mixture.

I have naturally and almost without noticing the transition passed to the last and most important head of my lecture—the application of our laboratory knowledge acquired on animals to clinical practice applied to ourselves. Not much time remains to me *for all there is to say; perhaps I may* be permitted to deal more fully with the many questions that come up for answer under this head on some future occasion.

The words "and the higher animals" have expressly formed part of the title of this lecture. Under "clinical practice" I include "veterinary practice." Personally I should be almost as willing to expend thought and money to insure the safe anæsthesia of a favourite animal that required operation as *to insure that of an unknown man*, woman, or child. Happily, however, there is here no antagonism of interests nor protection of commercial privileges at stake; here anything benefiting a dog or cat must also benefit man, and anything benefiting the man must also benefit his friends among the animals. Men have paid and are still paying a heavy price in return for the boon of anæsthesia conferred upon them 60 years ago by Wells, Morton, Soubeiran, Flourens, Simpson, and Snow. The annual returns of the Registrar-General *exhibit* the *picture shown in Fig.* 5 of the increasing price paid in human lives from 1863 to 1901. It is an unnecessary price, inasmuch as the chief reason of its payment consists in the ignorance of the most elementary principles of anæsthesia. Anæsthetists explicitly assert that they are not acquainted with chloroform in arithmetical terms, as 1, 2, 3, and 4 per cent., and that they judge of its power solely from its clinical signs and symptoms.

Experience is, no doubt, the great teacher. The empirical anæsthetist of to-day who has witnessed the clinical signs and symptoms presented by patients in danger of death, or actually put to death, under his method of administration is, no doubt, a less dangerous administrator than the instructed scientist quantitatively acquainted with the power and properties of anæsthetic agents. But the scientific man does not desire to trespass upon the domain of the practical anæsthetist; he only wishes to bring to the common melting pot his own contribution of experience in the belief that it will prove to be an important ingredient of the practical knowledge of future anæsthetists.

You may have heard about that worthy nurse who did not hold with "those new-fangled thermometers" but preferred to regulate the temperature of the bath by the colour of the baby's skin. She was probably a better nurse than some of her younger sisters—better acquainted with thermometers than with babies—not perfectly sure perhaps about Fahrenheit and Celsius—but she is certainly a still better nurse when she has learned to count on a bath-thermometer. Chloroform anæsthesia is of greater importance to us all, and *even an experienced anæsthetist is a safer anæsthetist if* he can count the chloroform he gives us, and if he is accustomed to think about chloroform in concrete numbers, instead of judging by symptoms only and recognising (or not) that a danger signal is in sight.

FIG 5.

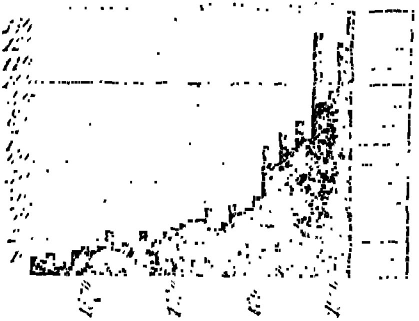

Diagram of the annual numbers of "deaths from anæsthetics" in England in the years 1863 to 1901 constructed from the returns of the Registrar General.

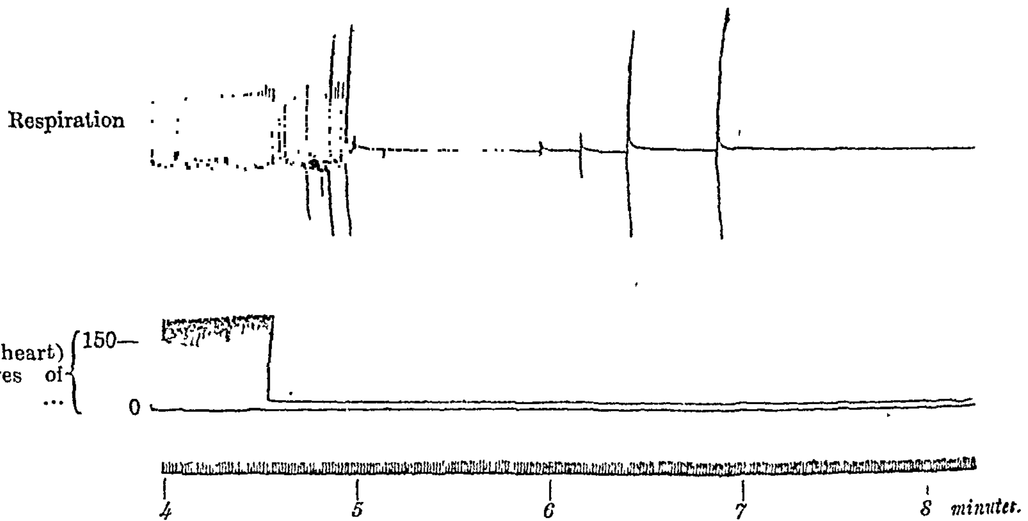
To return for a moment to the death-rate diagram. The unsifted figures of such returns are not, I am well aware, unimpeachable scientific evidence of actual numbers of deaths directly caused by anæsthetics. The numbers may be *too high or they may be too low, they may include cases not* caused by anæsthetics but that have occurred from other causes during anæsthesia; or they may fail to include actual cases of death really caused by anæsthetics, but certified—and quite honestly certified—as caused by that disease for which the services of the surgeon and of the anæsthetist had been invoked. And this remark is applicable to continental as well as to English returns. I think that the returns are, however, sufficiently voluminous to be amenable to the "law of large *numbers*" and to justify us in regarding the actual figures, inclusive of their plus and minus errors, *as fairly representative* of the state of the case as regards the death-rate by anæsthetics in past years. The figures are at least arranged by unprejudiced machinery, and I cannot but regard as disingenuous the assertion that such figures are worthless and the demand for their detailed analysis. Detailed analysis is impossible and even if possible would be *misleading*, for if faults of commission might be detected, faults of omission would be beyond correction. It can only be in a few cases that analysis and criticism are possible. I [illegible] the period 1896-7 in a presid[illegible] of Anatomy and Physiology [illegible]sociation held at Montreal si[illegible]quote from the year that has just elapsed two cases which, with full knowledge of the details of both cases, I characterise as unjustifiable accidents directly due to the maladministration of chloroform. The first case occurred in London and the second in Germany.

CASE 1.—A healthy, powerful man went to the out-patient department of a London hospital to have a piece of glass *removed from his hand, was chloroformed by the* "towel method" by the *dresser in charge, and could not be brought* round. The verdict returned at the coroner's inquest was "Death by misadventure."

CASE 2.—A young woman went into hospital to be operated upon for appendicitis. After due preparation and the patient being in an otherwise healthy state, chloroform was administered by the Esmarch method. Within a few minutes her heart stopped. The statement made in the medical certificate was "Death by syncope."

Both of these most lamentable accidents, which occurred during the last year in the limited circle of my own cognisance (I was not present), were the direct result of chloroform vapour ignorantly administered. No regard was paid to the concentration of chloroform in the air inspired; it may have reached any percentage short of the saturation point of a solution of chloroform vapour in air at the then room temperature. Presumably a deep breath or two of such a mixture were taken, whether few drops or many of liquid chloroform had been dropped on the towel in the first case and on the Esmarch mask in the second, and the wave of chloroform to the pulmonary sheet of blood overpowered the heart directly, or at least placed it in that critical state where any, even the smallest, bulbar disturbance from any afferent channel is to be dreaded. They were early deaths by primary cardiac syncope during the period of induction of anæsthesia; their mechanism is illustrated by this tracing of the blood pressure and respiration of a cat that was being anæsthetised by chloroform at 5·75 per cent. (Fig. 6.) Sudden arrest of the heart, causing sudden fall of blood pressure, took place in coincidence with the slamming of a door. I expressly use the expression "in coincidence with" because I cannot be certain that the slammed door was really the cause of the sudden cardiac arrest and I have failed to reproduce the accident in subsequent trials.

FIG. 6.



An early death by sudden cardiac arrest (primary syncope). Cat under chloroform at 5·75 per cent. No recovery possible. The four gasps apparent on the respiratory record are the terminal anæmic convulsions characteristic of a cardiac death. In the human subject they may arouse hope, whereas in reality they are the last sign of life.

In conclusion, let me repeat a statement made five years ago to the Society of Anæsthetists. "The evidence in point shows that it is necessary, and within reasonable limits of error practicable, to secure dosage in the administration of chloroform and I should like at once to characterise and earmark that argument by the statement that successful chloroform anæsthesia requires the regular respiration of air in which the chloroform vapour is maintained between the limits of 1 and 2 per cent." Nothing has happened within the last few years that should lead me to modify this statement.

The anæsthetics' death-rate as given in the Registrar-General's returns has not diminished. Cases of death in which it has been possible to analyse and to consider details of procedure remain as unpardonable as ever. And I have shown you as clearly as was possible that animals in a physiological laboratory are as a matter of course anæsthetised by chloroform safely as well as effectively.

What is the cause of the greater danger to which men, women, and children are exposed? Is it fear acting upon a nervous system more highly organised than that of animals, or "idiosyncrasy," or "impure chloroform"? These are perhaps contributory causes, but as I know from the experience of the laboratory that 5 per cent. is "dangerous" and between 1 and 2 per cent. is sufficient, I do not think it proper to give importance to possible secondary influences until the principal condition of safety has been secured.

PS. (Nov. 7th).—By the intermediation of my friend Dr. P. M. Chapman and through the courtesy of the surgical staff of the Herefordshire General Hospital I have received an opportunity of applying to the human subject in the operating theatre the method of anæsthesia that the experience of the laboratory has shown to be so satisfactory in the case of animals. Dr. Chapman will no doubt publish his notes of the clinical features of the cases. I may be permitted to state now that the cases were five in number and unselected, that the induction was effected in from six to ten minutes, and that anæsthesia of required depth was maintained for the required periods without untoward symptoms. The nominal delivery of the pump throughout was 2 per cent. (except in the first case, where it was commenced at 1·2 per cent.), and after the period of induction the percentage actually inhaled was reduced by occasional removal of the face piece. The total duration of the five administrations was 100 minutes, the total amount of chloroform employed was 100 cubic centimetres (= 30 litres of chloroform vapour), the total volume of air delivered by the pump was 1400 litres (30 in 1400 is equivalent to 2·15 per 100). Densimetric determinations of the delivery taken before, during, and after administration came out between the limits of 1·6 and 2·4 per 100. The determinations were made in an ordinary balance with a half-litre bulb and weights made by dividing two-grain slips of metal into eight parts; each eighth part (= a quarter of a grain) was taken as indicating 0·8 per 100. If I should have occasion to repeat such determinations I should prepare weights = one-eighth of a grain to represent steps of 0·4 per 100. For finer determinations it would be preferable to employ a skilled assistant.

On Nov. 16th, by the courtesy of Dr. F. W. Hewitt, and under his responsibility, I anæsthetised four unselected cases at St George's Hospital by the Dubois's pump. The induction at 2 per cent. was normal and uniform and was completed within the limits of five and ten minutes (except in the case of an infant when the period of induction was between two and three minutes). Anæsthesia of required depth and duration was maintained at 1·6 and 1·2 per cent., with occasional brief intermissions as judged desirable by Dr. Hewitt. The delivery of the apparatus as tested by densimetry immediately before use was as follows:—

Nominal percentage.	Observed percentage (averages of four trials).
2·0	1·975
1·6	1·600
1·2	1·188

ABSTRACT OF

An Address

ON

THE PRESENT STATE OF THE IRISH POOR-LAW MEDICAL SERVICE.

Delivered at St. Vincent's Hospital, Dublin, on Oct. 6th, 1903, at the Opening of the Medical Session,

BY R. F. TOBIN, F.R.C.S., M.R.C.P. IREL.,
EXAMINER IN SURGERY, ROYAL COLLEGE OF SURGEONS IN IRELAND; SURGEON TO ST. VINCENT'S HOSPITAL, DUBLIN.

[AFTER a few introductory remarks Mr. Tobin said :—]

Thinking of a special subject for this address the two that present themselves to me as being uppermost in our minds at present are the state of the weather and that of the Irish Poor-law medical service. Both are equally bad but as the weather is a more difficult and more of a medical subject I shall leave it for Dr. McHugh next year and consult with the lately qualified students as to whether they should or should not take dispensary appointments under the present conditions. This subject is not grateful to me. First, it is threadbare. Had I all the eloquence of the Irish Bar it would not be possible to say of it anything more or in a better way than has been said by others—notably by my colleague Mr. McArdle from this very desk five years ago. Secondly, I have to commend to you a line of action that is foreign to us alike as men belonging to a generous race and a generous profession. However, this matter is pressing. There is unanimity amongst us that something must be done to improve the position of Irish Poor-law medical officers and therefore I think that it is the duty of each one of us to bring the subject before the public on every possible occasion and to continue to hurl truisms and commonplace facts into the street till those in authority give active consideration to them. What is the case of the Poor-law medical officers? A price, they say, was put on our services which at the time it was fixed was certainly not too high. Since then the cost of education has doubled and our market value has doubled, yet we are refused any increase either of privileges or pay.

[After quoting from an article on the medical profession which appeared in the *Cornhill Magazine* of June, 1903, Mr. Tobin continued :—]

In this paragraph is to be found the explanation of the present discontent. A man after five or six years of arduous study and after seeing many fall upon the way completes his course. He takes employment in the Poor-law medical service and he find himself treated as regards pay and consideration as if he were a Bob Sawyer. The inadequacy of the pay of the dispensary medical officer has been set forth in various ways. For instance, it has been shown that in many districts if these medical officers were allowed merely the rate of car-hire given to other Government officials and no pay whatever they would be better off than they are now. To myself the condition of things was brought home very forcibly in this way.

[Mr. Tobin here quoted a case showing the superiority of the army medical service over the Irish Poor-law medical service even before the inauguration of the improved condition of the former. He went on :—]

Now, as regards the cause of the present quarrel—and indeed of all quarrels where the profession demands higher terms than the public are prepared to give—when we look closely into it we find that it is due to the fact that while we offer to the public certain high-class goods, not low in price but of excellent value, what they, the men in the street, want from us is a low class article that would be dear at any price. You who have been recently qualified or are about to be so have probably uppermost in your minds as regards your profession ideas such as the following. You find yourselves anxious to go on adding indefinitely to the knowledge you now possess, to put that knowledge at the service of the public for payment when you can, gratuitously when occasion demands, and whether for payment or no payment never to give anything but your best. But form what conception you may of your rôle in life you will find a large number of the public, a number daily growing larger, who have made up their minds as to what they will have of you and you will deny it to them at your peril. In the minds of such men the medical man seldom looms larger than one who prescribes a mixture, a pill, or a blister, to which armoury have of late been added Roentgen rays and tabloids. It has been so in the past; it is so to-day with the cultured as well as with the illiterate.

Let us take cases. We always study here from cases. Now if I ask you to look back through the last few centuries and to tell me what man stands out pre-eminently as a great block of sense I have no doubt most of you will answer Dr. Johnson. His wisdom is embodied in our household words. He stands great because he *was* great and because Boswell has preserved him for us in a living shape. It is a life one never tires of reading. Every first-year student should buy that book and, dividing it into parts, have it bound up with Birmingham's "Anatomy," Kirkes' "Physiology," and Tobin's "Synopsis of Surgery." For surely it is not by anatomy and physiology and surgery alone that a man grows wise—no, nor even by a study of Fraser's great work on the topography of the brain—but by keeping himself in touch, as far as he can, with the great men past and present in every branch of literature and of art. Well, anyhow, Johnson was a wise man except on the subject of medicine. Having had a "paralytic stroke" he writes to Mrs. Thrale as follows: "I suppose you may wish to know how my disease is treated by the physicians. They put a blister on my back and two from my ear to my throat, one on a side. The blister on the back has done little and those on the throat have not risen. I bullied and bounced (it sticks to our last sand) and compelled the apothecary to make his salve according to the Edinburgh dispensatory, that it might adhere better. I have now two on my own prescription. They also give me salts of hartshorn which I take with no great confidence. But I am satisfied that what can be done is done for me." Is not that true to life or rather to sickness? You see it is to the blisters as amended by himself, made according to the "Edinburgh dispensatory," that he pins his faith. These adhering he feels—oh! thrice blessed phrase—that "what can be done is done." That once said, whatever the result the physician walks out with his head in the air

That is Case 1. Now for Case 2 Once upon a time a young fellow just married bought a practice in a manufacturing district in England where I was quartered. He gave for it £1000, the fortune he got with his wife—being at the rate of one year's purchase. He was probably a St. Vincent's man, for he knew his work well and was full of enthusiasm and the highest ideals. At the end of 15 months he moved away with his wife but without her fortune. Asking the people amongst whom he practised the cause of his failure I was told that he was a humbug and that he knew nothing. Why, it was said "he would sometimes take a quarter of an hour to examine you, whereas the man he bought the practice from could see his job the moment he looked in your face." To be looked in the face and to get a bottle were all they wanted from their medical attendant.

The third case is more up to date. It presented itself while I was sitting a few days ago in a railway carriage, in the shape of one of [illegible] during the first pa[illegible] people present and people not present. For instance, he told a lady who said she had a child at home with a sore-throat to give him a tabloid, which she could get at any druggist's, of five grains of phenacetin and to repeat the tabloid in three hours when she would find all the symptoms relieved. After this he read for a time his evening paper and struck by something in it he turned to me and said: "Now, doctor, how do you account for the high mortality of Dublin?" Seeing me trying to hide a smile in my book he added: "It is no laughing matter, my dear fellow."

Now, gentlemen, if the Irish poor are to be treated simply with blisters that will stick, or with mixtures after they have been looked in the face, or with tabloids after they have described the nature of their disease, we are, I think, all agreed that the pay of the dispensary medical officer is sufficient for the occasion. But is this, then, the practice of medicine? It is not the practice of medicine as it was generally known in Ireland till we became infected with ideas from across the water. We are continually being told how they manage things better in England and how our system of medical relief pauperises the people. The facts are that unhappily a large number of our people *are* paupers or so poor that no decent man would expect a fee from them, but it was not the medical profession which made them so. Secondly, in no land does the medical profession stand higher or conduct its practice better than in Ireland. At a time when in England a medical practitioner had to take his way through the back door of his wealthy patients his fellows in Ireland were associating on terms of perfect equality with everyone in this land. Why is this? Simply because we have always treated, and the public have always encouraged us in treating, our rôle in life as a profession and not as a trade.

Now, what is the difference? Well, you will find one in the resolution which I took for granted just now was in the minds of each of our newly qualified men—viz, that whether for large fees or small fees or no fees at all he would never give anyone he prescribed for anything but his best. Now, this requires in most cases a full examination of your patient and a careful consideration of his case. There is a sum of money, it may be two guineas or one guinea or 5*s*., which taking into account your position, your necessary expenditure, and other things, fairly represents what has been done. If you take less you are inclined to scamp your work. I speak not absolutely but with the relativeness which applies to all things human. Well, so working always at your best you establish a habit; there is but one class of article in your shop and if a poor person comes along you give him either that article or nothing at all. The well-to-do public, at least the more enlightened of them, join with us in taking this view of the question. They see that they must suffer from any deterioration in our profession, that they are often benefited by the skill gained by those who practise amongst the poor, and this combined with less selfish motives makes them satisfied to pay fees not based on purely mercantile considerations. So there comes to be between the well-to-do, the poor, and the medical men a mutual helpfulness, the interchange of which constitutes the salt that saves us from putrefaction.

[Mr. Tobin here referred to counter prescribing as not necessarily objectionable and continued:—]

Now that motor-cars are about a better idea of things may become prevalent. When a man has spent three hours on his back looking up into the works of his car, taking it to pieces and putting it together again, and then walks sadly to the nearest railway station, the complexity of some machines, amongst which he may rank the human body, may dawn upon him, and with it may come an inkling that the human body cannot be properly attended to when out of order for a sum that a mechanic would refuse for almost any job. But as all have not motor-cars would it not be well if the profession were to formulate what it considers the province of a dispensary medical officer to be, and to hold up this definition before the public on every occasion? It is, however, no easy task to do so in a clear and simple way. In place of defining its limits it is easier to ask, whither do they not extend? What is it which does not influence our health? The air we breathe, the water and food we consume, the work we do, the sights we see, the games we play, everything which acts upon us comes within the scope of the medical practitioner. This is no vague generalisation but a hard practical fact. The cultured and well-to-do are, it is true, becoming educated in domestic hygiene, but it is not so with the poor. To limit the treatment of their ailments to a bottle of medicine is a mockery and a crime. The part therefore that the dispensary medical officer has to play is a very large one. He is many specialists in one. There is practically no limit to the good he can do if he is a man of sense, ability, and skill. It is his to guard against the occurrence of disease, to limit its spread, to help those attacked in their struggle with it, to raise the physique and to forward in every way the comfort and well-being of those committed to his care. This is no mean task and surely the man who is called upon to undertake it may put forward the three demands of the Irish Medical Association—viz, firstly, a competence (£200 a year) while he works; secondly, a moderate pension when he is no longer able to do so; and thirdly, a month's leave of absence every year in which to recuperate his health or to attend a post-graduate course so as to keep himself *au courant* with the advance of science.

At the outset of this address I remarked that the necessity to remedy the present condition of things is urgent. There is, however, another reason for pressing on with energy just now. It is that we have in office a Chief Secretary and an Under Secretary possessing, as we believe, the will and the ability to help us. Their records fill us with hope. How can we best lay our case before them? If only you, Mr. Chairman, could take them for a drive in a motor-car through the scenes of your early labours. It would be a pleasant tour, for it would be through many beautiful places, but it would also be a sad one, for at every turn there would be something speaking to thoughtful minds of present misery and neglected opportunities. The ruined cabins on the hillsides must awaken thoughts of the brave men born and reared in them and so of battles fought and battles yet to be, of a chain of emigration so much gone over the ship's side that one stands in dismay lest the whole should follow. With these thoughts uppermost you would naturally turn to see what was being done to preserve the remaining few. In the houses you enter there is not much of all that the twentieth century is proud of. On every side you see signs of disease spreading unchecked. The young maimed or dying from tuberculous disease, the old dying from cancer; lunacy on the increase; typhoid and typhus fever calling forth heroism and striking down those who display it. Perhaps in some cottage you may come across a dispensary medical officer doing what he can to cope with the difficulties. It may be a sore-throat which if not isolated at once would spread diphtheria or scarlet fever far and wide—one which my friend of the railway carriage would treat with five grains of phenacetin; or it may be a crippled child for whom a Thomas's splint is necessary. If the latter, the medical officer will be trying to collect 25*s*., the price of the splint. No doubt the Chief Secretary will give £1. Perhaps when you get outside he may ask, "Where will the other 5*s*. come from?" Be sure you tell him the custom of the country, "The doctor will give that himself," and do not fail to add, "and well he may out of his fine salary."

A dispensary medical officer: what a quantity, what a vast, unmeasurable quantity, of grand unselfish work is covered by that name. Here and there, it is true, are to be found a few careless and intemperate in many ways. The casual observer is impressed by them, he goes his way ignoring the hundred others who day and night are expending their best energies in the service of the poor. Some pathetic incident gives the general public a glance at this everyday life and they forthwith stand amazed at the heroism therein displayed. It does not detract from the honour of those who wear the Victoria Cross to say that thousands who have shown an equal bravery are going unregarded through life. Could we but resuscitate and have amongst us for this occasion the late Mr. William Smyth of Burtonport, how his manly heart would respond and glow with pride to my saying that the work he died in doing is being done in the same heroic way by practically every dispensary medical officer in Ireland whenever occasion demands. To how many a one could not we who know them apply the words of Browning inscribed on a tablet erected in Templecrone Church in memory of Mr. Smyth:—

"One who never turned his back, but marched breast forward,
Never doubted clouds would break,
Never dreamed, though right were worsted, wrong would triumph,
Held we fall to rise, are baffled to fight better,
Sleep to wake."

In saying this I am not indulging in mere verbosity. I am simply stating matters of fact. From the *Londonderry Sentinel* of August 25th I learn that at least Dr. Brendan MacCarthy, a man of whom we at St. Vincent's Hospital are justly proud and who worked with Mr. Smyth on the memorable occasion two years ago, is still marching as he had always marched, "breast forward." I read from that paper:—

> Dr. MacCarthy, addressing the guardians, said, as they were aware, typhus had reappeared in Arranmore. He was on the island last week and visited not only the houses in which the outbreak occurred but the houses upon which he had occasion last year to report unfavourably and he did not find any real improvement. Typhus fever was essentially a disease of dirt and overcrowding. It was the scourge of gaols and armies before the [illegible] of cleanliness and air space was understood. Typhus w [illegible] ace of the globe because it could not stand for [illegible] fresh air, and soap and water. But in different parts of Ireland [illegible] ouses were of an unhealthy description. The windows were not of a proper or sufficient size to let in God's [illegible] the floors were of clay, the roof defective, and the wal [illegible] was huddled and crowded in the house, and la [illegible] s, with which they were all familiar. Those wo [illegible] eeding typhus and naturally they had outbreak [illegible] very cause for such was there, and very plain [illegible] n, when there was such a loathsome and infectious [illegible] in the house, the priest or the doctor who went into that house did so at the imminent

risk of his life. But that same case could be visited and nursed with comparative safety if the fresh air and sunlight were allowed to come freely into the house and dilute the poison.

[After comparing the attention given by the State to munitions of war with its neglect of the individual man Mr. Tobin concluded as follows:—]

The all-importance of the issue and the lethargy of our rulers necessitate, and constitute the justification of, the attitude of the profession towards the Irish Poor law medical service. Not in the interest of the individual—though his lot, however inadequately set forth by me, is hard indeed—not in the interest of the profession, but in that of the public weal do I say to you: join the Irish Medical Association and, for the present at least, leave the Poor-law medical service alone.

Presidential Address

ON

SOME QUESTIONS IN SEASIDE CLIMATOLOGY.

Delivered at Westgate-on-Sea before the British Balneological and Climatological Society on Oct. 30th, 1903,

BY ALFRED F. STREET, M.A., M.D., D.P.H. CANTAB.

> "ὦ δῖος αἰθὴρ καὶ ταχύπτεροι πνοαί,
> ποταμῶν τε πηγαί, ποντίων τε κυμάτων
> ἀνήριθμον γέλασμα, παμμῆτόρ τε γῆ,
> καὶ τὸν πανόπτην κύκλον ἡλίου καλῶ."
>
> "[illegible]
> On you I call"

GENTLEMEN,—When I realised that one of the duties of the responsible office to which you have done me the honour of electing me would be the production of an address I decided that I would attempt to deal with some topic relating to the sea. For inspiration I consulted an eminent Fellow of the society and his reply was as follows: "I should consider the factors of a bracing climate, because yours is about the most pronounced specimen of the sort that I know." What follows will therefore concern certain questions which have long and deeply interested me with regard to the air of the north east corner of Kent in which I have the good fortune to live, air which the late Dr. Ord has called "singularly pure and invigorating," and which Dr. I. Burney Yeo tells us has "important tonic properties," a locality of which Dr. W. Ewart wrote that it has a soil drier than almost any other in England, which is the last to be visited by the storms which come to us from the Atlantic, which owing to the absorbent qualities of its soil has its land wind more than usually free from moisture, which enjoys almost the full advantage of the warmth of the Gulf Stream and in this respect excels the more northerly east coast watering places of Great Britain, and against which his only indictment is that it is "hyper-ventilated," for it is on record that the average number of calm days in the year is only 38. That close observer, the late Sir James Paget, said to me nearly 20 years ago that his experience was that many scrofulous patients would get well there when they would not get well elsewhere. He frankly admitted that he could not say what special property the air had but as to its effects he entertained no doubt, and though his claim may not be universally admitted that point may be waived.

[illegible] d I hoped to [illegible] has not come [illegible] -day point to facts which may to some extent explain the essential causes of differences of climate such as do not find full explanation by the barometer, the thermometer, and the other ordinary [illegible] For it has been very truly said [illegible] ke so there are no two places [illegible] The factors of climate are [illegible] distance from the equator; (2) the distance from the sea; (3) the height above the sea; and (4) the direction of the most prevalent winds. But this is only a very partial statement of the truth; for instance, it takes no cognisance of so potent a factor as the Gulf Stream to which we in these islands are indebted for the advantage that though London has the latitude of Labrador it has a far higher mean winter temperature. Nor does the statement that "weather spells climate" carry the whole truth, for there are many other factors in climate, at any rate in local climate, which after all is what chiefly concerns our patients. Besides such local influences as the Gulf Stream there are the configuration and inclination of the land; the character as to porosity or drainage of the soil; the presence or absence of vegetation, of cultivation, of plantations, or of forests; the degree of protection afforded by trees, by mountain ranges, or merely by higher ground in the vicinity; the density of population, the neighbourhood of manufactories and their nature, and so on. It would be *more true to say that* climate depends upon soil, air, temperature, moisture, solar radiation in all its many forms, and possibly on electrical and other even less known conditions. Can we make any notable advance towards that clearer insight which enables us to replace empirical by rational knowledge?

In considering the claims of any locality with reference to the cure of any disease the first question which presents itself is, to what extent the disease in question prevails among those born and bred in the locality? If we take scrofula as an example it must be conceded that the north-east corner of Kent, for instance comes out exceedingly well. Those who practise there find very little home grown tuberculosis and imported cases commonly do well. In the face of the prolonged experience of many careful observers extending over many years it would surely be unreasonable to deny the claims of various localities to be credited with various cures, and the further question arises as to what factor or combination of factors a particular locality owes its influence. We all know that in the case of a spa the popular answer is "to the waters" and in the case of most seaside places "to the air." When a visitor comes to the seaside it matters not whether he feels better or worse. The cause so far as he is concerned is "the air"; perhaps he calls it "the strong air." He does not know what he means by the epithet "strong" but it has the advantage of being capable of conveying either praise or blame. Indeed, one constantly finds it considered capable of producing diametri- [illegible] people. One has diarrhœa. [illegible] "the strong air." Another [illegible] his personal negligences [illegible] and so on. But we here have no concern with the vox populi; we seek for facts and for legitimate deductions from them and, finally, if possible, for explanations of them.

We cannot credit the air alone with antituberculous virtue, we must give due weight to sunshine and dryness of soil and to many other climatic factors. Relative humidity is a very thorny subject not now to be especially considered, but its importance may be judged from the calculation that every pound of water condensed from vapour liberates heat sufficient to melt five pounds of cast iron. Yet it does appear that there is in the air of certain localities a quality which cannot be expressed by chemical symbols and yet of which some of us are conscious. I cannot better express it than by the term "briskness," for it is not coldness, neither the coldness measured by the thermometer nor the other coldness so especially appreciated by the skin. It is felt by night as well as by day and is therefore not wholly dependent upon sunshine. It is most pronounced during the prevalence of winds which are not westerly and which have come from over the sea either directly or nearly so. It has been truly said that "each health resort is distinguished from all others by [illegible] its own," and the more closely [illegible] ore differences do we find beyor [illegible] of latitude and longitude; in fact, Professor A. Buchan declares that "we are only on the threshold of a rational inquiry into the true character of seaside climates." We are told by a writer in the last number of our journal that "few seaside places are really bracing," but he will not carry that proposition *nemine contradicente.*

Let us now consider how geographical position affects the physiological effects of air. Is there, for example, a greater percentage of ozone? Now ozone has long occupied a commanding position in this connexion but one of the objects of this address is to submit to you that ozone is, like many other prominent folk, an impostor. There is no question of denying its existence or of doubting its constitution, nor its willingness to part with its odd atom in the good cause of oxidation, but is there convincing evidence that it is produced in nature except during thunderstorms as was known to Homer by what he calls the smell of the thunderbolt? In a recent article Professor Abbé asserts that there is no such evidence. Yet its presence should be determinable beyond doubt since Hartley, Chappuis, and Schöne agree in saying that it has a definite absorption spectrum. Professor W. A. Miller wrote as follows: "The existence of traces of ozone in the atmosphere, probable though it is, cannot be said to have been unequivocally proved." Other observers have asserted that it is formed in nature in various ways. Thus M Peyron found that papers moistened with a solution of starch and iodide of potassium and suspended over a patch of growing lucerne acquired a deeper colouration than similar papers similarly suspended over a neighbouring plot of ground free from vegetation. Now this test was hopelessly discredited years ago, for it can easily be proved that such papers react to peroxide of hydrogen and to nitrous acid and to other bodies often present in the atmosphere, and that unless the iodide of potassium has been freed from iodate even the carbonic anhydride of the air in presence of water will discolour the paper. There is the further difficulty that the so-called iodide of starch is said to be volatile, especially in presence of much moisture, and, at any rate, ozonoscopes are found to fade on continued exposure. The fact is that no satisfactory test for ozone in air has yet established its position.

It is asserted that ozone is formed when electricity is generated by the friction of waves beating on rocks, it has even been asserted that it is formed during the combustion of carbon in air. There are many other tests for it, such as red litmus paper moistened with a solution of iodide of potassium, paper moistened with a solution of thallous hydroxide which it turns brown (probably peroxide of hydrogen does the same), or by one of manganous chloride, and in the laboratory chromic acid will decompose peroxide of hydrogen and not ozone, but this test has not been applied to the atmosphere.

Again, ozone may be distinguished from both peroxide of hydrogen and nitrous acid by the red colour which, according to Erlwein and Weyl, it alone gives with metaphenylene diamine in the presence of an alkali, but this, too, has not been used in the case of atmospheric air. From spectroscopic observations Schöne concludes that there is no more than a probability of its presence in the atmosphere, and Sir W. Ramsay, a great authority on subjects connected with the atmosphere, states in a recent work that "the occurrence of ozone in the air is still a matter of dispute." Yet most books on climatology not only confidently assert its presence but distinguish between places and seasons in which it is more or less prevalent. Thus we are told that there is more in mountain air than in sea air and *vice versâ*, and more in the spring than at other seasons, and more in forests than over plains, and one third more in air from over the sea than in that from over the land, and it is stated by Würster that it is formed by the action of sunlight on clouds and by silent atmospheric electrical discharges. Though the ozone produced by electricity in the laboratory is destroyed by heat this is probably due to the fact that the electricity has subjected it to strain and that it has thus been formed in excess of the equilibrium value for ordinary temperatures. Guntz believes that he has shown that the ozone formed by lightning is generated not by the electricity but by the heat which results from the electrical discharge, and Professor Nernst at the recent German Congress of Applied Chemistry has pointed out that owing to the enormously high temperature and great gravitational pressure the oxygen in the sun is probably wholly in the condition of ozone, and this view is borne out by the fact that being an endothermic body it becomes more stable the higher the temperature to which it is raised. So ready is ozone to part with its loosely attached atom and so universal is the presence of oxidisable matter in the localities where ozone is said to be produced that it is hard to understand how sufficient can escape destruction to enable us to detect its presence except perhaps by means of the spectroscope, for it is said that it is never present in greater quantity than 1 part in 700,000 It would indeed relieve us of many of our sanitary difficulties if ozone were produced by nature in large quantity.

Apparatus for the production of ozonised air in the sick-room is advertised by instrument makers, but apparently the demand for it, and perhaps also the utility of it, is not very great, for according to the late Sir B. W. Richardson even small percentages of ozone in inspired air cause inflammation of the respiratory tract, and it is possibly for this reason that it does not seem to have been considered advisable to add it to the oxygen which is manufactured for use in cases of pneumonia. Oudin asserts that the inhalation of ozonised air causes a rapid increase in the hæmoglobin of the blood, though he does not indicate how this is effected. In places where the difficulty of dealing with dead seaweed is insuperable it is locally said to exhale ozone, and I remember that on visiting a resort where the retreating tide exposed many acres of sewage-polluted mud I was asked to believe that the mud generated ozone. The so-called ozone of pine forests may be due to peroxide of hydrogen, but there is evidence that it is camphoric acid and not ozone at all.

In connexion with the claims of ozone there are those of peroxide of hydrogen to be considered, but we know scarcely more than that chemists have been aware of its existence in atmospheric air since it was discovered by Schönbein in 1840 He found that it was formed together with ozone during all the slow oxidation processes in course of which the latter is formed and also during its electrical production. It has no smell. It has been found by Clermont in most unexpected places—in vines, in lettuces, and even in tobacco juice. There are special chemical reasons for believing that it is present in the atmosphere, for Fenton has shown that tartaric acid in the presence of iron gives when exposed to air and sunshine the characteristic reactions of dioxymaleic acid, and he finds that sunshine and air may in this reaction be replaced by peroxide of hydrogen but not by ozone nor by nitrous acid, so that he very plausibly argues that peroxide of hydrogen is formed by the action of the sun on the air. But books on climatology disregard it and no one seems to have concerned himself about its influence whether climatological or physiological, though Meissner in 1863 claimed to have detected its constant presence in atmospheric air and Struve found it in water and in snow. There is not much probability that it will succeed to the reputation which ozone does not deserve, though such influence as it has is no doubt good, because like ozone it is always ready to hand on its extra atom of oxygen.

It has been supposed that the chloride of sodium diffused in the air by spray from the sea has a tonic effect but it seems hardly reasonable to think that a very minute quantity of a chemically inert body should have an important effect on the body which is permeated by fluids which contain it in plenty. Iodine and bromine have also been brought forward, but in what compounds and in what quantities we are not told, and considering the usual medicinal doses of their compounds the quantities possibly present in the air must be quite unimportant. A consideration of what is known of argon, helium, krypton, neon, and xenon shows them to be extraordinarily inert, for they are said to form no known compound and therefore to have no polarity. One is inclined to wonder if there is not here an exception to what is said to be the only undisputed maxim in philosophy—namely, "Natura nihil agit frustra"—but in the hands of Professor G. D. Liveing and Professor J. Dewar the spectroscope has shown that in the case of krypton at any rate the maxim still holds good, for krypton is probably responsible for one of the green rays of the aurora borealis. The same observers tell us that in the spectrum of the gas which separates from atmospheric air solidified by liquid hydrogen, and which has so far proved to be incondensable, there are a vast number of rays which are most brilliant at the violet end and which belong to elements hitherto unidentified. This spectrum suggests the presence of more than one unknown substance in the most volatile portion of the atmosphere Can there be here any gas of climatological or physiological importance? Is there a yet undiscovered element minute as it must be in proportion but potent in action? When we remember the wonderful properties of the most minute fragment of a compound of radium or the powerful physiological action of very small fractions of a grain of hyoscine or of adrenalin it is not impossible to think that an element or compound as yet unknown may be responsible for important therapeutic effects.

Professor Buchan tells us that the fundamental element of climatology is the temperature of the air. Only 50 per cent. of the total solar radiation due, so to speak, on a given area at the sea level ever reaches that area. Even when the sun is at the zenith the amount which arrives is very much less than 100 per cent. and by no means all of this is heat, especially as our atmospheric envelope is more transparent to the rays of shorter than to those of longer wave length Now the temperature of this air is one of the few things we need not argue about for it has been observed daily steadily and systematically for some 23 years by the indefatigable observers of the Royal Meteorological Society The maxima, the minima, the average, and many other data are on record, and the facts are that the average daily range is moderate (namely, 11 3° F), as that of every seaside place must be owing to the moderating influence of the sea, and that the average temperature equals that of London, partly no doubt owing to the fact that the sunshine average is over 20 per cent more at the former than at the latter place Owing to the influence of the Gulf Stream aided by the preponderating prevalence of south west wind the winter isothermal lines of Great Britain lie nearly north and south instead of east and west The isothermal line of January slants across England from Dover to North Wales and passes thence along the west coast of Scotland The greater frequency of barometric variations near the sea may tend towards the attainment of that perfection of organic life which is said to depend on the alternations of excitement and repose

There remains to be mentioned hydrogen which is undoubtedly present in our atmosphere , but for every gas there is an altitude at which as many molecules diffuse outward as inward in unit time, and recent physical deductions lead to the conclusion that such hydrogen as the earth exhales, so to speak, into its atmosphere from the pores of certain minerals leaves the extreme confines of our atmosphere on its way through interplanetary space to join the atmosphere of the sun, the gravitational attraction of the earth's mass being overcome by that of the sun, but even if it stayed with us it is not clear what physiological effects it would have except as a diluent of oxygen

Is there a greater percentage of oxygen in sea air than in land air? I know of no evidence that there is, though Dr Angus Smith found 0 92 per cent more than the average in the air of the Western Highlands, and though volume for volume there is of course more oxygen in sea air than in mountain air But if there be any such preponderance, however small, it would be likely to exert a stimulating effect, just as we know that a small decrease of the normal proportion of oxygen is depressing and it is certain that there are variations in the proportion of carbonic anhydride Thus there is less in exposed than in sheltered places and less in air from over the sea than in that from over land, more by night than by day, and more in summer and winter than in spring and autumn Just as it is not possible to predicate the therapeutic effects of a given water from a consideration of a laboratory analysis of it, so it is not at present possible to explain the difference in physiological effect between the apparently similar air of different places At one of the earliest meetings of this society Dr W V Snow very rightly told us that it was not so much to the composition of a water that we must look as to the results upon the patient that experience had shown could be obtained We must not neglect the teachings of experience only because we cannot explain them and this applies to air quite as much as to water, and we have to remember that the best chemical analysis would be eluded by a hitherto unrecognised element, and it is only recently that the very existence of several normal constituents of the atmosphere has been established Helium is an apparently inert element but is it certain that its presence and that of argon in the water of one of the Bath springs have no influence on the therapeutic effects of that water? Can it be certain that it is there merely in solution? If not it may in combination be capable of results as astonishing as those of some compounds of the typically inert nitrogen

Is it lawful to surmise that some as yet unknown element gives its peculiar character to the air of some localities or shall we find our explanation in the new and mysterious property introduced to us by Becquerel as radio activity? It is true that hitherto the chief sources of radium and polonium, the best known of the radio-active bodies, are minerals such as pitch blende and chalcolite and not the ocean, but Wilson has proved the existence of a radio-active substance in filtered rain water and in snow and hail, especially during a thunderstorm, and it is not destroyed by heating the containing vessel to dull redness Professor J J Thomson has extracted at least two radio-active gases of great density from many different deep well waters and has shown that their radio activity is different in kind from that of radium in that they render radio active a negatively electrified surface and not an unelectrified one Strutt finds radio activity to be widely diffused and that there is some in most metals Sir Oliver Lodge surmises that radio active emanations (the so called α rays) which are believed to consist of actual atoms of matter may proceed from many substances without our being yet aware of their existence Rutherford and Allen have found that a negatively charged body exposed in the air becomes radio active and they conclude that therefore there is some radio active substance in the atmosphere Sea water has not, it seems, hitherto been subjected to examination as to its radio active properties, but it is reasonable to suppose that in this respect it is more likely to resemble well water than surface water Before the discovery of radio activity Dr Julius Hann wrote "There can hardly be any doubt that there are still other modifications in the composition of the atmosphere which have some influence on the human organism but which have not yet received any attention"

May we expect [illegible] variations in the electrical [illegible] localities which Dr S E [illegible] nt? The mysterious and elusive character of electricity and magnetism tempts us to ascribe to them any characteristics which are apparently not otherwise explicable, just as the ancients invoked the aid of magic, and it may be that we shall find in them the answer to this problem, for undoubtedly some people are especially sensitive to abnormal atmospheric electrical conditions and it has been experimentally shown that strawberries ripen sooner and in greater numbers when grown under the influence of an electrical field A beneficial effect has been observed in the case of plants grown under one of the poles of a Wimshurst machine and this cannot be ascribed to ozone, which is formed chiefly at the positive pole, whereas the plants in question did best near the negative pole Elster and Geitel have arrived at the conclusion that free ions exist in the atmosphere and if this is so they may be of physiological importance Now we are told that the average amount of electrical force is least when the wind comes from a point midway between north and north-north west—that is to say, from a point midway between the true and the magnetic north poles—and yet this is the wind which seems to me to deserve more than any other the epithets brisk, bracing, and stimulating But Professor P G Tait writes that "our ignorance of the source of atmospherical electricity is singularly complete"

Let it be granted, then and granted I think it must be, that the atmosphere of some localities has special properties, and let it be admitted that we cannot at present express these properties in terms of any known element or force, then there arise two questions Firstly, in what circumstances are these properties therapeutically valuable? and secondly, can we in any way preserve intensify or diffuse [illegible] wer the first of [illegible] seems appo ite— [illegible] al conditions are of little moment apart from personal comfort.' On the other hand what patients would derive benefit from such a climate and for what patients would it be undesirable?

When we try to work out the answer to these questions we find ourselves in the position of the medical man who is called upon to prescribe a diet not for a disease but for a patient It is comparatively easy to prescribe for an abstract disease—that is what the text books do—but how difficult for a concrete patient and one, too who probably has strong and inconvenient leanings and antipathies or idiosyncrasies such, for example, as an unusual sensibility to diminished atmospheric pressure similar to the case of cats which, according to Dr Burney Yeo, cannot be acclimatised in certain localities of high elevation The determination of principles for the selection of climates is one of the most vitally important services which this society can render to our profession, for it is impossible to trust most of the hard-and fast rules which are offered for our guidance Is it not rather common to hear a patient say 'I was sent to such and such a place but I hated it all the time I was there,' or "I went and I did all the doctor told me to do and I came away worse than when I went." If not an *opprobrium medicinæ* this is at any rate an *opprobrium medici* and when we have taken off a large discount for the exceptionally foolish and the merely mistaken, is there not an appreciable residue? The public, of course, label places with the names of certain diseases just as they label consultants and there is a real difficulty before us when we try to avoid the same pitfall.

May we not rightly argue that owing perhaps to the strain and stress of modern existence and the constantly increasing proportion of town-dwellers there is more need for, and advantage to be gained from, a climate which is stimulant than from one which is sedative, from strychnine rather than from bromide of potassium? Dr. Burney Yeo maintains that sea air makes less demands upon the organism than does mountain air. A late president of the American Climatological Association describes sea air generally as a "sedative tonic" and he sums up as follows: "Considerations so many and so difficult enter into the fitting of an individual case to the particular climate that it would be a futile effort to prescribe special climates for special diseases." Nevertheless, we may say, as Dr. Leonard Williams has recently very forcibly said, that in the case of some diseases certain climatic combinations are to be avoided. There are constitutions in which a stimulant atmosphere produces a feeling of general discomfort and there are people who have idiosyncrasies with respect to climate just as others have with respect to drugs.

Now just as those who make the fewest mistakes in the prescribing of diet are those who consider the likes and dislikes and who know the ordinary mode of life of a patient, so shall we most successfully give advice in respect of climates if we carefully consider not only the name of the patient's disease but his climatological likes and dislikes. The man of open windows is likely to thrive best in stimulant air and the man who is sensitive to draughts may be better suited by a more sedative climate, for in some persons the automatic control of the vaso-motor system is clearly either undeveloped or too slow. Nor can we afford to lose sight of the great importance of aspect. How often it happens, especially in the spring, that there is one climate on the north side of a wall and another on the south side. There is no need to insist on the need of avoiding dry cold wind in cases where damaged kidneys are able to do only part of their duty or for pulmonary cases enfeebled by prolonged suppuration, nor does anyone in England need to be reminded that one cannot in England reckon on summer weather in summer time nor, indeed, upon winter weather in winter time. Most children are the better for a stimulant climate and of the people best suited by a sedative climate a large proportion are aged.

My second question is soon answered. "Man," it has been truly said, "cannot change the weather by any device yet suggested," not even by American methods of rain production, yet he does affect climate by removing trees (for vegetation increases the humidity of the air, though not the actual rainfall) and by drying the soil by works of drainage, or by supplying it with water as by means of the Assouan dam, and by the cultivation of previously barren spots. We can preserve the life-giving properties of our air by cultivating the highest ideals in sanitary matters. It is of little use to live at the seaside with shut windows and in air used up by overcrowding and fouled by dust and by pestilential sewers and filthy dustbins, and it is universally admitted, or should be so, that a dry subsoil and clean underground air are essential to high sanitary excellence. Parasitic microbes grow most readily in warm, moist places and it has been calculated that in the course of a single day a man inhales 10,000 litres of air, so that determinations of the number of living micro-organisms present in the atmosphere at the ground level at once assume great importance. Now it has been shown on the one hand that an adult in Manchester inhales in the course of ten hours 37,000,000 microbes and that in London there are present from 80,000 to 210,000 solid particles in each cubic centimetre of air, and on the other hand that in the air of the Western Highlands the corresponding number is only 16. In these respects a great responsibility rests upon our profession, the responsibility of helping to educate and to influence not only our patients as such but all who hold office in the public bodies by which we are more or less misgoverned.

Finally, I would ask you to assent to this proposition. The places in our islands which enjoy most often a pure and *stimulating* atmosphere are those the air of which comes most often from over the sea. The more directly it comes from the sea and the longer it has been away from land the more pure it is. Its stimulating properties depend partly upon its relative humidity, partly upon its temperature, and partly upon factors not yet thoroughly understood. "I speak as unto wise men, judge ye what I say."

A Lecture

ON

PATENT MEDICINES.

Delivered at the London Hospital Medical College on Nov. 10th, 1903,

By ROBERT HUTCHISON, M.D. EDIN., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STEET, W.C.

GENTLEMEN,—On a previous occasion I have considered with you the merits—and also the demerits—of the various patent foods and I have asked you to meet me to-day in order that we may study together the kindred subject of patent medicines. I have done so because I feel strongly that this is a subject upon which you ought to be informed. You will be expected by your patients to give opinions on these preparations and your opinion cannot be an intelligent one unless you know something of their composition. And if it should be your duty, and in my judgment it often will be your duty, to condemn patent medicines, you must be prepared to give a reason for the want of faith that is in you. That must be my excuse for burdening you with yet another lecture.

The first question we have to ask ourselves in approaching this subject is, what is meant by a patent medicine? How should one define the term? Now in the legal acceptation of the word a patent medicine should comply with two requirements. It is laid down in the law of the subject first, that it must be a genuine original invention; and, secondly, that a complete description of it must be filed at the Patent Office so as to be easily obtainable by the public. I need hardly say that neither of those requirements is fulfilled by the majority of the preparations to which the term "patent medicine" is applied. If you consider the former—namely, that the preparation must be a genuine original invention—I have merely to read you an account of some patent medicines that I have collected from the records of the Patent Office to show you to what extent such a description is applicable. I find, for instance, that in July, 1892, a patent was taken out for a specific for the alleviation of asthma or bronchial affections, of which the following is the recipe: "Steep crushed eggs in lemon juice so as to dissolve the shells, add some rum and strain." That may be an original invention, gentlemen, but whether it is likely to be curative of asthmatic affections I think is extremely doubtful. In October, 1890, a medicine was patented for the cure of pulmonary affections which is directed to be made by mixing one gallon of extract of cloves, a pound and a half of honey, and one pound of brown sugar-candy. In February, 1895, a certain Mr. Richardson showed great originality by taking out a patent for a medicine for the cure of rheumatism, which consisted of a mixture of sodium salicylate and water. I need not trouble you with further examples other than to mention the original idea of the gentleman who took out a patent for some pills which were to counteract the effect of taking too much alcohol, the pills consisting of powdered coffee. So much for the first of these requirements, that it shall be a genuine original invention. And I need hardly point out to you that the second requirement—namely, that a full description shall be published so as to be readily obtainable by the public—is one which is not likely to be observed in practice. For obvious reasons it is one which would hardly commend itself to the average patent medicine vendor. Hence it is that the majority of so-called patent medicines are not so in the legal sense at all; they are much better defined as secret remedies or nostrum (from the Latin word which means "belonging to us alone"), and I would remark in passing that this word "nostrum" breathes a spirit which is entirely opposed to what is one of the finest traditions of our profession—namely, that if anyone discovers a method of treating a disease which he believes to be new and successful he publishes it at once for the benefit of the profession at large. That is entirely opposed to the meaning of the word "nostrum," and that is where we, the legitimate healers of the public, come into direct conflict with the spirit which animates the charlatan or quack. I think, indeed, that it would not be unfair to decribe most of the preparations of which I shall have to speak as "quack" remedies. On referring to a standard dictionary I find that a quack is defined as "one who cries like the common domestic duck," "one who makes pretensions to knowledge, particularly medical knowledge, which he does not possess." And I think it is not unjust to apply such a description to most of the people who sell the so-called patent medicines.

I turn next to consider the question of the stamp duty which is levied on patent medicines. In the year 1783, when the Exchequer was depleted after the war with the American colonies, the then Chancellor of the Exchequer looked around for sources from which to raise revenue, and he decided that patent medicines would be legitimate objects of taxation. Carrying out that idea a tax was levied by means of a stamp placed upon the bottle or box, and many of the preparations which I have upon the table show such a stamp. The ignorant part of the public naturally supposed that anything which bore a Government stamp must be something of peculiar value and presumably genuine, but it was not until the year 1885 that an effort was made to dispel that idea by printing upon the stamp the words, "No Government guarantee" Whether this addition has succeeded in its intended object is, however, more than doubtful. Such is the history of the introduction of the stamp duty on patent medicines and nostrums Recently the Board of Inland Revenue has recognised that a number of preparations are escaping the payment of the stamp duty and it has tried to spread wider its net and to make such preparations pay duty also, for there has always been a degree of uncertainty as to which were taxable. In a recent decision by Mr. Justice Wills[1] it was laid down that remedies which are taxable are those which are recommended for the cure of any particular ailment. If, for instance, a man sells a box of pills labeled "antibilious pills" that thereby renders the box liable to stamp duty, because the word "antibilious" means that the pills are intended to cure the particular condition known as biliousness. On the other hand, with that extraordinary want of logic which often characterises things legal, such a mixture as "soothing syrup" is exempt from duty because it does not specify exactly what it is intended to soothe The same is true of "tonic mixture," because no indication is given of what it is designed to tone up. That is at present the law on the subject, so far as I understand it. I do not anticipate that this extension of the duty to preparations which are intended to cure particular diseases will do much to discourage the use of patent medicines, but it will certainly add to the revenue obtained by their sale; and one is surprised in these days of tariff reform that the makers of patent medicines do not form a "Free Medicine League" and advocate the entire removal of duties from patent medicines, pointing out to the public the advantage of the large medicine bottle as opposed to the small!

Such being the history of the tax on patent medicines we may next look at their composition. I have placed in your hands a sheet which represents the approximate composition of a considerable number—but not by any means all—of the better known patent and proprietary preparations or nostrums. I wish it to be clearly under-tood that my analyses make no pretence to perfect accuracy. The analysis of many of these preparations, particularly such as are of vegetable origin, is often a very difficult matter and it has been found impossible to give quantitative results I believe, however, that I have succeeded in representing the active constituents in most, if not all, cases.

APPROXIMATE INGREDIENTS OF VARIOUS PATENT AND PROPRIETARY PREPARATIONS.

Aperient and Liver Pills.

Beecham's Pills—Aloes, ginger, and soap.
Baillie's Pills.—Aloes, colocynth, oil of cloves, and soap.
Bile Beans—Cascara, rhubarb, liquorice, and oil of peppermint, coated with gelatin.
Cockle's Pills and Barclay's Pills—Aloes, colocynth, and rhubarb
Carter's Little Liver Pills.—Podophyllin (one eighth grain) and aloes soc. (one-third grain) in each pill.
Dixon's Pills.—Taraxacum, podophyllin, jalap, and soap.
Holloway's Pills—Aloes, rhubarb, saffron, Glauber's salts, and pepper.
Page-Woodcock's Wind Pills—Aloes, oleum carui, and soap.
Scott's Pills.—Aloin and cascara with a soap basis.
Whelpton's Pills.—Rhubarb, aloes, ginger, pulv. ipecac., and soap.

Saline Aperients.

Eno's Fruit Salt.—[illegible] of potas- [illegible] phate of magnesium, and sugar.

Cough Mixtures and Lozenges.

Congreve's Elixir.—Benzoic acid, infusion of elderberries, alcohol, and allspice.
Keating's Cough Lozenges—Ipecac., lactucaria, squill, liquorice, tragacanth, and sugar.
Owbridge's Lung Tonic.—Balsam of tolu, oil of aniseed, and oil of cloves
Balsam of Aniseed—Contains aniseed and other ingredients with one-tenth of a grain of morphia in every ounce

Preparations for Gout and Rheumatism.

Eade's Pills.—Salicylate of sodium, guaiacum, and aloes.
Gloria Tonic—Colchicum, guaiacum resin, and iodide of sodium.
Blair's Gout Pills.—The active ingredient is colchicum.

Preparations for Headache and Neuralgia.

[illegible] cannabis [illegible] of tolu, and alcohol.
Kapuline.—Antifebrin and sugar (coloured).
Kay's Tic Pills.—Sulphate of iron, quinine, and soap.

Preparations for Asthma.

Crevoisier's.—Belladonna, foxglove, stramonium, sage, and nitrate of potassium in equal parts.
Hair's Cure.—Iodide of potassium and tar water.
Plant's Cigarettes.—Leaves of stramonium, lobelia, and green tea.
Tucker's Cure.—Atropine, cocaine, hyponitrous acid, and various balsamic extracts, administered by means of an aeriser.

Remedies for Obesity.

Trilene Tablets.—Sugar and a vegetable constituent of unknown nature.
Grey's Specific—Contains 47 2 per cent of free sulphur and a bitter (? gentian)
Mrs. Frost's Anti Obesity Remedy—The active ingredient is extract of fucus vesiculosus.
Russell's Anti Corpulent Cure.—Citric acid (20 grains to half an ounce), glycerine, and water. The Pink Tablet = saccharine.

Miscellaneous Preparations

Bucr's Piles Cure—Ointment Gall and hamamelis with lanoline basis Powder: Precipitated sulphur and carbonate of magnesium.
Californian Syrup of Figs.—Senna (active constituent), syrup of figs, [illegible] (liver pills) [illegible] coated (back- [illegible] benzoin). [illegible] of gentian and chloroform water
Dalby's Carminative—Pulv. rhei, magnes. carb., glycerine, sugar, [illegible] potas- [illegible] chloroform water
Pink Pills—Sulphate of iron, an alkaline carbonate, and liquorice, [illegible] grains to the [illegible] anethi, sugar, [illegible]

Drink Cures

Mrs. Terry's.—Sugar (98 per cent.) and salt (2 per cent).
Antidipso.—Chlorate of potash and sugar.

For convenience I have divided the various preparations which I have examined into different groups. The first comprises the aperient and liver pills which are amongst the most largely used of all patent medicines. The popularity of this group is a sign of the immense prevalence of chronic constipation and all its attendant ills. You will observe that most of these pills contain aloes as one at least of their active ingredients. Now aloes has, as you know, been long recognised as a useful habitual laxative and to most of the members of this group no objection can be raised on the ground of composition. Many of them are skilfully compounded and undoubtedly possess the aperient action to which they lay claim, but I need hardly point out that prevalent though constipation is it is by no means the only possible cause of all the symptoms which most of these preparations are supposed to be able to cure. The saline aperients are all effervescent preparations consisting of bicarbonate of soda on the one hand and tartaric acid or citric acid on the other. They are "elegant" and pleasant saline laxatives—only that and nothing more. The most striking point about the cough mixtures is that their makers have recognised what we, I am afraid, are sometimes slow to recognise—that most coughs are due to irritation of the pharynx and not to affections of the bronchial tubes. In most of them, therefore, the "demulcent" constituents predominate. That they are well adapted to relieve a pharyngeal cough need not be doubted, but that they can exert any curative influence in such a disease as phthisis is, of course, a mere delusion. The preparations for gout and rheumatism present one point of special interest. Colchicum and salicylate of sodium one is not surprised to find in them, but I confess that I was rather surprised to find that two of them contained guaiacum. And yet I believe the makers are right. Guaiacum is a drug which has probably fallen too much into disuse amongst ourselves. At all events, speaking from my experience in the out-patient room, I can confidently say that I have often found it afford great relief in chronic gout and in the so-called chronic rheumatism of old people. The preparations for headache and neuralgia are mostly of recent introduction and depend, to a large extent, upon a judicious exploitation of the virtues of the coal tar derivatives. The indiscriminate use of some of these is certainly not devoid of danger. Remedies for asthma have long been popular with the patent medicine vendor, and some of them, it must be admitted, have attained a wide and not undeserved reputation. I have indicated the composition of a few typical specimens, the composition of which, however, is already pretty well known.

---

[1] *Times* Law Reports, No. 22, vol. xix.

The obesity preparations have given me more trouble than any of the others. In the case of some, at least, I was entirely unable to discover the exact composition. I fully expected to find that some of them would contain thyroid extract but in that I was disappointed. One of them consisted mainly of extract of fucus vesiculosus (bladder-wrack) which has long been believed to have a tendency to diminish stoutness, though its claims rest on no very strict scientific basis. Another consisted chiefly of citric acid, which is interesting when one remembers the popular belief that sucking lemons makes one thin. As regards several of the others I confess to being puzzled. This only I must say in fairness, that I had the curiosity to write to some of the people who had supplied testimonials to the makers of these remedies and found that, so far as I could discover, the testimonials were genuine and that those who supplied them believed at least that their weight had been reduced by the medicine. I can only say that I wish I knew of any remedy which could be counted upon safely to reduce weight in the absence of any change of diet.

Under "Miscellaneous preparations" I include a number of interesting and widely known nostrums of which, however, I have not time to speak in detail. This only I would point out, that a preparation which depends for its activity on iodide of potassium cannot be described as harmless; nor is one which contains considerable quantities of nitrate of potassium in any true sense "safe." Of "drink cures," perhaps the most objectionable product of the quack, I have examined only two. Their composition, unless I have entirely overlooked some other ingredient, is more eloquent than any words of mine could be. I would only say that in each case the preparation is intended to be given as a powder smuggled into tea or coffee without the patient's knowledge and is alleged to remove the craving for alcoholic drink and that for 24 little packets of the former I had to pay 5*s*. Oh, the eternal gullibility of the British public!

If, then, gentlemen, as the analyses have shown, these preparations contain nothing new and nothing mysterious why is it that they are so popular and that the revenue from their sale amounts to no less a sum than £300,000 per annum? I think, in the first place, that this popularity points to the existence of a great deal of minor illness for which people do not think it worth while to consult a medical man. To this I do not see that we have any reason to object because we cannot hope to possess a monopoly of attempting to cure people. It is open to anyone who thinks he can do it to try to cure somebody else if that person is foolish enough to allow him to try his hand; and so long as diseases exist people will try to find remedies for them without the intervention of the medical man. That one must admit. But apart from that I think there is a subtle psychological reason for the success of patent medicines. None of us like to confess that he has failed in the treatment of a case and that is specially true of the man who tries to cure himself. A patient buys a bottle of patent medicine and becomes his own physician. If he gets well he is immensely pleased with himself and at his discrimination in selecting (as he thinks) the proper remedy and he goes and tells his friends what a clever fellow he is. But if he fails and feels no better as a result of the purchase he says nothing about it. Hence the successes of patent medicines get talked about and their failures are buried in obscurity. By far the chief reason, however, of the success of patent medicines is, as I need hardly point out, persistent and audacious advertisement. The extent to which such advertisement is carried is almost incredible. Even in the middle of last century, which was before the great days of advertising, the patent medicine people were early in the field. It is said that when Dickens was at the height of his fame a firm of patent medicine makers offered him £1000 if he would mention their pills in one of his novels. He declined. When this was told to Thackeray he said that it was foolish to refuse, for he could have pocketed the cheque and killed off the villain with an overdose of the pills!

The subject certainly has its humorous side, but of many of these advertisements it is difficult enough for us who know the facts of disease to speak in temperate terms. It seems to me monstrous that people should be allowed for their own ends to produce in the public mind a true pathophobia or exaggerated dread of disease, to raise false hopes in the unfortunate sufferers from incurable maladies, and to obtain money from those who can often ill afford it by holding out illusory promises of cure. If people assert, for instance, that pills containing sulphate of iron and bicarbonate of potash will cure tabes, or that pain in the back is frequently a symptom of renal disease, they are saying a thing which is not true, and if they sell a remedy on that basis then if that is not getting money under false pretences that phrase has lost its meaning. Against such a state of things we ought as a profession to protest. The time is ripe, indeed, it is over-ripe, when we ought to make some organised effort against it and I look forward to the day when there will be appointed a committee or official body of some sort, representing, say, the British Medical Association or the General Medical Council, whose business it will be to inquire into the composition of these so-called remedies and to expose them. I do not think it is right that this should be left to the initiative of private individuals; it is a matter which concerns the profession as a whole. I am afraid, however, that the time is still far off when that will come about and in the meantime we must all do what we can in our private capacity to fight this evil. I believe, gentlemen, that there are two ways in which we can do so. First of all we must educate the public. After all, people still look to us, and rightly, to inform them about these as about other matters relating to their health. If necessary, we may have to educate the public in the elements of physiology so that they will realise what at present they seem incapable of realising, that the same set of symptoms may be produced by many totally different diseases, and will distrust the man who claims to have some panacea which will immediately effect a cure no matter what may be the cause. But if we are going to begin such a process of education we must begin at the top. Believe me, quackery is not confined to any particular section of the community; it would be entirely wrong to suppose that it is found simply among the more ignorant classes. It is as rife, nay, I venture to say it is more rife, in Belgravia than it is in Bethnal Green. The upper classes, the so-called cultured classes, have a belief in patent medicines and quackery generally which is almost incredible. And if we are ever to get legislation on the subject we must begin by educating our legislators.

The other weapon for fighting this evil we already have in our own hands. It ought never to be possible for a patent medicine vendor to say with truth that he has succeeded in curing a case where a medical man has failed and if he is to be unable to say that it means that we must give more attention to the treatment of disease, and particularly the treatment of minor ailments, than I think we do at the present time. You who are here have the opportunity in this great hospital of studying scientifically the diagnosis and treatment of disease and I ask you to use it well

I take blame to myself that one does not always explain the treatment of cases in the wards as carefully as one might, perhaps because there is so much else to do. But in the out-patient room here you have an immense material for study, embracing examples of every form of disease. See to it that yor gently and wisely, and if that when you go out int to fear the competition of the charlatan and the quack.

ON ALBUMINURIA AS AN ACCOMPANIMENT OF DIABETES MELLITUS.

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

ALBUMINURIA has long been recognised as a frequent accompaniment of diabetes but widely different estimates of the frequency of the association have been given by different authorities. It is not surprising that this should be the case as grounds exist upon which variability may arise. Much depends upon the closeness and the exactness with the albumin is looked for. Much also depends upo length of time attention is given to the case that is the subject of observation and upon the class of case that is dealt with. Should the record be founded only upon one or two observations the absence of albumin might have to be reported, whilst if the observations had been carried on over a lengthened period its presence might have to be entered in connexion with the case. Cases also in an advanced stage of the disease are more likely to be attended with associated albumin than those belonging to an earlier period. It may be considered sufficient to say that albuminuria without any doubt constitutes a notably frequent accompaniment of diabetes. No useful purpose is served by going further. The frequency of the association is such as to preclude its constituting a merely incidental phenomenon and it is not permissible to do otherwise than conclude that there must be a connecting link between the two. Diabetics are not exempt from the supervention of other maladies as independent affections and, no doubt, albuminuria sometimes holds this position in connexion with diabetes, but it is inconceivable that it can do so in more than a minute proportion of the instances that present themselves. If we look at the cognate disease—diabetes insipidus—we do not meet with the supervention of albuminuria in the manner we do with *diabetes mellitus*. There is an absence of a factor which may be regarded as of prime importance—viz., the abnormal transit of sugar through the system.

Before proceeding further with the subject matter to be dealt with I will take the opportunity that is here presented of offering some remarks upon the clinical examination of the urine and of giving the results of my own experience upon the point. At a former period I entered closely into the question of the relative merits of the various tests for urinary albumin and came to a conclusion which time has only served to strengthen. Innumerable tests have been proposed and fresh ones continue still from time to time to be suggested. Only a few can lay claim to eligibility when looked at all round and amongst these the ferrocyanic test occupies, I consider, a first place in most satisfactorily meeting what is wanted. For many years it has been employed as my ordinary test and experience therefore enables me to speak with precision about it. In chemical works it is highly commented upon as a delicate and reliable test for albumin. Acetic acid and the ferrocyanide of potassium are the agents ordinarily employed. In applying the test to the urine the acetic acid in small quantity is first added and then the solution of ferrocyanide of potassium is dropped in. Ferrocyanic acid is liberated and if albumin is present a precipitate appears. The test ranks as one of the most sensitive known and at the same time one the reaction of which is least likely to lead to a fallacious conclusion. There are certain principles, nucleo-proteids (including mucin), uric acid, and oleo-resinous matter from drug administration, that are liable to be thrown down by any acid, no matter whether organic or inorganic, and these may appear as a precipitate from the ferrocyanic test; but no real difficulty is here encountered, all that is necessary to guard against fallacy being to use the acetic acid first and to take note before using the ferrocyanide if any sign of precipitate appears. If a precipitate does appear it cannot consist of albumin. It is only the precipitate that falls as a result of the addition of the ferrocyanide that does so. If any doubt exists comparative testing may be had recourse to in a couple of tubes, one with the acetic acid alone and the other with the acetic acid and ferrocyanide. It frequently happens that nucleo-proteid and albumin are present together. When this is the case the nucleo-proteid is thrown down in the tube with the acetic acid alone and the albumin is revealed by the extra amount of precipitate noticeable in the tube where the ferrocyanide is present. I consider a great advantage belonging to this test, in addition to its other qualities, is the avoidance it affords of the employment of anything of a corrosive nature like, for instance, nitric acid. Further, the test is susceptible of being put into the portable form of pellet. Many years ago Mr. Cooper, of 66, Oxford-street, at my suggestion, made these pellets for supply to the profession and they have ever since been sold by him. The citric takes the place of the acetic acid for one pellet and the other pellet consists of the ferrocyanide of sodium, this being used on account of its giving a product which dissolves with much greater facility than the potassium salt. In the n, in which it is always con- is necessary is first to drop dissolve, and then to drop in the other and similarly shake and dissolve, when the result becomes at once apparent. By the lamina method of testing a recognisable indication may be afforded when none is perceptible with the ordinary mode of procedure. This test lends itself well to this mode of application. A few of each of the pellets are dissolved in a small quantity of water in a test-tube so as to produce a concentrated solution, on to the top of which the urine is trickled down. The faintest amount of albumin is in this way brought into view by the lamina formed at the line of contact of the two liquids, and with the ferrocyanic test an indication may be perceived when none is discernible with nitric acid used in a similar way, on account of the obscuring effect of the colour that may be developed in the latter instance.

Since the introduction of the centrifuge the microscopic examination of the urine has been placed upon a much more satisfactory footing than it held previously. It is certainly a great advantage to be able to carry out the chemical and microscopic examination of urine at the same sitting as can now be done. Centrifuging for seven or eight minutes is found to suffice for fully meeting what is wanted. Whilst the hand machine may be made to serve the required purpose where no other power is available, much tedium and labour are saved by the adaptation of water or electric power. Two or three years ago I obtained from Messrs. R. and J. Beck, of 68, Cornhill, a centrifuge worked by an electric motor connected with the house electric supply and nothing could be desired to answer better. I should say from my experience that besides the advantage afforded in relation to convenience the centrifuge gives greater reliability to the examination than is otherwise attainable.

In albuminuria as a concomitant of diabetes the amount of albumin is ordinarily not large; indeed, more frequently than not only quite small. An appearance is sometimes given of an increase occurring with the decrease of sugar arising from the effects of treatment. It may happen when a case first falls under observation that only a slight indication of albumin is perceptible. Later a much more pronounced precipitate is noticeable. With this, however, the urine has become diminished in amount, and here lies the explanation of the apparent increase. In proportion to the decrease in the amount of urine so is the apparent increase in the amount of albumin. It stands as a result of lessened dilution.

As I have said, experience shows that albuminuria is of notably frequent occurrence in association with diabetes. From this it may be taken that some condition or other connected with diabetes tends to affect the kidney and to lead to the production of albuminuria. It does not, however, follow that in all instances this is the case. Albuminuria may become developed in the diabetic from the causes that lead to its development in the non-diabetic and thus constitute a purely independent affection. In this way we may have albuminuria on the one hand occurring simply as a concurrent malady, and on the other as a consecutive phenomenon attributable to the diabetes. As a rule, a supposed to be able to cure. The saline aperients are all effervescent preparations consisting of bicarbonate of soda on the one hand and tartaric acid or citric acid on the other. They are "elegant" and pleasant saline laxatives—only that and nothing more. The most striking point about the cough mixtures is that their makers have recognised what we, I am afraid, are sometimes slow to recognise—that most coughs are due to irritation of the pharynx and not to affections of the bronchial tubes. In most of them, therefore, the "demulcent" constituents predominate. That they are well adapted to relieve a pharyngeal cough need not be doubted, but that they can exert any curative influence in such a disease as phthisis is, of course, a mere delusion. The preparations for gout and rheumatism present one point of special interest. Colchicum and salicylate of sodium one is not surprised to find in them, but I confess that I was rather surprised to find that two of them contained guaiacum. And yet I believe the makers are right. Guaiacum is a drug which has probably fallen too much into disuse amongst ourselves. At all events, speaking from my experience in the out-patient room, I can confidently say that I have often found it afford great relief in chronic gout and in the so-called chronic rheumatism of old people. The preparations for headache and neuralgia are mostly of recent introduction and depend, to a large extent, upon a judicious exploitation of the virtues of the coal tar derivatives. The indiscriminate use of some of these is certainly not devoid of danger. Remedies for asthma have long been popular with the patent medicine vendor, and some of them, it must be admitted, have attained a wide and not undeserved reputation. I have indicated the composition of a few typical specimens, the composition of which, however, is already pretty well known.

The obesity preparations have given me more trouble than any of the others. In the case of some, at least, I was entirely unable to discover the exact composition. I fully expected to find that some of them would contain thyroid extract but in that I was disappointed. One of them consisted mainly of extract of fucus vesiculosus (bladder-wrack) which has long been believed to have a tendency to diminish stoutness, though its claims rest on no very strict scientific basis. Another consisted chiefly of citric acid, which is interesting when one remembers the popular belief that sucking lemons makes one thin. As regards several of the others I confess to being puzzled. This only I must say in fairness, that I had the curiosity to write to some of the people who had supplied testimonials to the makers of these remedies and found that, so far as I could discover, the testimonials were genuine and that those who supplied them believed at least that their weight had been reduced by the medicine. I can only say that I wish I knew of any remedy which could be counted upon safely to reduce weight in the absence of any change of diet.

Under "Miscellaneous preparations" I include a number of interesting and widely known nostrums of which, however, I have not time to speak in detail. This only I would point out, that a preparation which depends for its activity on iodide of potassium cannot be described as harmless; nor is one which contains considerable quantities of nitrate of potassium in any true sense "safe." Of "drink cures," perhaps the most objectionable product of the quack, I have examined only two. Their composition, unless I have entirely overlooked some other ingredient, is more eloquent than any words of mine could be. I would only say that in each case the preparation is intended to be given as a powder smuggled into tea or coffee without the patient's knowledge and is alleged to remove the craving for alcoholic drink and that for 24 little packets of the former I had to pay 5*s*. Oh, the eternal gullibility of the British public!

If, then, gentlemen, as the analyses have shown, these preparations contain nothing new and nothing mysterious why is it that they are so popular and that the revenue from their sale amounts to no less a sum than £300,000 per annum? I think, in the first place, that this popularity points to the existence of a great deal of minor illness for which people do not think it worth while to consult a medical man. To this I do not see that we have any reason to object because we cannot hope to possess a monopoly of attempting to cure people. It is open to anyone who thinks he can do it to try to cure somebody else if that person is foolish enough to allow him to try his hand; and so long as diseases exist people will try to find remedies for them without the intervention of the medical man. That one must admit. But apart from that I think there is a subtle psychological reason for the success of patent medicines. None of us like to confess that he has failed in the treatment of a case and that is specially true of the man who tries to cure himself. A patient buys a bottle of patent medicine and becomes his own physician. If he gets well he is immensely pleased with himself and at his discrimination in selecting (as he thinks) the proper remedy and he goes and tells his friends what a clever fellow he is. But if he fails and feels no better as a result of the purchase he says nothing about it. Hence the successes of patent medicines get talked about and their failures are buried in obscurity. By far the chief reason, however, of the success of patent medicines is, as I need hardly point out, persistent and audacious advertisement. The extent to which such advertisement is carried is almost incredible. Even in the middle of last century, which was before the great days of advertising, the patent medicine people were early in the field. It is said that when Dickens was at the height of his fame a firm of patent medicine makers offered him £1000 if he would mention their pills in one of his novels. He declined. When this was told to Thackeray he said that it was foolish to refuse, for he could have pocketed the cheque and killed off the villain with an overdose of the pills!

The subject certainly has its humorous side, but of many of these advertisements it is difficult enough for us who know the facts of disease to speak in temperate terms. It seems to me monstrous that people should be allowed for their own ends to produce in the public mind a true pathophobia or exaggerated dread of disease, to raise false hopes in the unfortunate sufferers from incurable maladies, and to obtain money from those who can often ill afford it by holding out illusory promises of cure. If people assert, for instance, that pills containing sulphate of iron and bicarbonate of potash will cure tabes, or that pain in the back is frequently a symptom of renal disease, they are saying a thing which is not true, and if they sell a remedy on that basis then if that is not getting money under false pretences that phrase has lost its meaning. Against such a state of things we ought as a profession to protest. The time is ripe, indeed, it is over-ripe, when we ought to make some organised effort against it and I look forward to the day when there will be appointed a committee or official body of some sort, representing, say, the British Medical Association or the General Medical Council, whose business it will be to inquire into the composition of these so-called remedies and to expose them. I do not think it is right that this should be left to the initiative of private individuals; it is a matter which concerns the profession as a whole. I am afraid, however, that the time is still far off when that will come about and in the meantime we must all do what we can in our private capacity to fight this evil. I believe, gentlemen, that there are two ways in which we can do so. First of all we must educate the public. After all, people still look to us, and rightly, to inform them about these as about other matters relating to their health. If necessary, we may have to educate the public in the elements of physiology so that they will realise what at present they seem incapable of realising, that the same set of symptoms may be produced by many totally different diseases, and will distrust the man who claims to have some panacea which will immediately effect a cure no matter what may be the cause. But if we are going to begin such a process of education we must begin at the top. Believe me, quackery is not confined to any particular section of the community; it would be entirely wrong to suppose that it is found simply among the more ignorant classes. It is as rife, nay, I venture to say it is more rife, in Belgravia than it is in Bethnal Green. The upper classes, the so-called cultured classes, have a belief in patent medicines and quackery generally which is almost incredible. And if we are ever to get legislation on the subject we must begin by educating our legislators.

The other weapon for fighting this evil we already have in our own hands. It ought never to be possible for a patent medicine vendor to say with truth that he has succeeded in curing a case where a medical man has failed and if he is to be unable to say that it means that we must give more attention to the treatment of disease, and particularly the treatment of minor ailments, than I think we do at the present time. You who are here have the opportunity in this great hospital of studying scientifically the diagnosis and treatment of disease and I ask you to use it well of, sugar till 1898, when a small amount, from 7 to 8 per 1000, was found This afterwards disappeared The urine, I note, was free from sugar in 1900 In 1902 a small amount was present and at the last interview, on June 8th, 1903, a little, but *less than at the previous examination*, was discovered The restricted diet has been throughout studiously and in a most determined way adhered to No albumin has been at any time detected and no bodily appearance is presented of the existence of diabetes

Looking upon the toxicity of the sugar traversing the system as the prime factor at the bottom of the albuminuria it should follow that more or less relationship between the two should be traceable, and such, from a broad point of view, it may be said, *is found to be the case* At the same time, however, there is sufficient diversity in particular instances to show that there must be some other factor playing a part in connexion with the matter and it may be presumed that the constitutional predisposition, as in other circumstances of an allied nature, contributes a share in the determination of the result We know that predisposition is capable of exerting a *marked influence in connexion with disease*, and it is conceivable that with the sugar in the system acting as the prime cause a modifying influence may be exerted upon the result by the constitutional disposition existing The following cases illustrate the amount of diversity that may be met with

Although not usual it may happen that albumin soon shows itself after diabetes has set in Much as regards this depends upon the character of the case with respect to severity In a case (a man, aged 26 years) which had set in sharply and suddenly two weeks previously and which was attended with very acute symptoms the urine, besides being highly charged with sugar and giving a reaction with the ferric chloride test contained a trace of albumin In a female patient, 35 years of age, after the existence of diabetes in an uncontrolled and severe form for six months, traces of albumin with hyaline casts were *found in addition to diacetic* acid and the *sugar* In a boy, aged 13 years, after diabetes had existed acutely for nine months, the urine contained traces of albumin accompanied with granular casts The acetone series of products were present in large amount in association with the sugar *In a young man, aged 23 years*, when first seen by me a year and nine months after the onset of the disease in an acute form, the urine, besides sugar and the acetone series, contained a faint trace of albumin and revealed the presence of hyaline and granular casts In another case, that of a woman, aged 43 years, when *I* first saw her on April 8th, 1903, the urine to begin with was free from albumin but contained a large quantity of sugar Diacetic acid and acetone were also present From the history given her diabetes had presumably existed about nine months The patient possessed an anxious temperament and notwithstanding some improvement at first she *failed* afterwards to make satisfactory progress Up to August the urine was free from albumin but in October it contained a trace accompanied with granular and hyaline casts

In the chronic class of case the diabetic condition may run on for a long time before albumin appears if it does so at all Much depends upon the extent to which the sugar is kept down and if not kept within moderate bounds sooner or later albumin may be expected to appear When a case is persistently and pretty closely watched it is often to be noted that when albumin has commenced to show itself it is found for awhile to be at times discoverable and at other times not, before it becomes continuously present The following cases may be cited to show the kind of course that may be witnessed to be taken

CASE 4 —The patient was a woman who was 64 years old when first seen by me She had been the subject of diabetes for ten years At first she made satisfactory progress and there was then no albumin to be found in her urine After

under and in

itself After

etimes not it

became persistently present in small amount A brother of *this patient has also* been under my care for diabetes I first saw him in May, 1894 at which time he was 64 years of age His disease has been fairly kept under control and his urine had not, up to May, 1903 given any indication of the presence of albumin

CASE 5 —The patient, a man, was first seen by me on Sept 29th, 1885 He was then 48 years of age His disease was of recent and mild onset and for a long time there was no difficulty in keeping the urine free from sugar by moderately careful attention to diet He even regained carbohydrate assimilative power sufficient to enable him to take as freely of ordinary bread as he desired without passing sugar *Later* a retrogression occurred and a reduction of the amount of bread was required to prevent the appearance of sugar in the urine This reduction was not always carried out and sugar became more or less constantly present in the urine In these circumstances the decline of assimilative power advanced and in the course of time the urine always contained sugar, and sometimes a large quantity when much dietetic deviation, as happened now and then, occurred In this way matters proceeded till 1899, 14 years after the patient's first visit to me, when a little albumin became discoverable in the urine In 1900 diacetic acid became also present and at the last interview, in October, 1902, I note that besides the sugar a trace of albumin, diacetic acid, *and acetone are recorded as having* been found

CASE 6 —This patient was a woman, aged 57 years at the time of the first interview on *Dec 24th, 1887 Diabetes* had existed for one year and the

of sugar but was free from al

and

afterwards maintained and a

presence sometimes of a very

large amount of sugar, ran on Previously to 1899 there was only an occasional record of a trace of albumin but after that time albumin was persistently found and in somewhat larger quantity The last entry is for Dec 9th, 1902 Granular casts had then made their appearance

CASE 7 —This patient was a woman who was 37 years of age when I first saw her on June 13th, 1891 She presented a family history of diabetes and from her personal history she had herself probably been the subject of diabetes in a mild *form for about six years* She was not on a properly restricted diet and her urine contained a considerable quantity of sugar It also contained a slight trace of albumin The sugar fell and I observe from the entry in December, 1891, that there was then none present I likewise notice that upon no occasion after the first till 1896 was albumin found and then a sharp increase of the diabetic state had set in From this time onwards albumin was invariably discovered and in the entry for the last interview, in June, 1903 it is

casts were recognisable

to be noted in connexion

ries of products had not

as yet become present

CASE 8 —The p

ears old when

he first fell under

diabetes was

of about six montl

a severe one

Up to 1894 nothing *specially out of the usual* course was noticeable except perhaps *a less active advance of the disease than is general at the patient's age* The urine was then free from albumin but upon a few occasions previously traces were noted as having been found In 1895 the patient was still living but in a very weak state The urine at this time contained traces of albumin in *conjunction* with the sugar which was only moderate in amount. I now lost sight of the patient till 1901, when I received a letter from Dr Bond of Havant informing me that the patient had been for some time under his care and that he was still living, though *reduced to an extreme state of* emaciation and weakness His diabetes had lately entirely disappeared and the fact was brought to light in an interesting and peculiar way In the summer of 1900, through atony of the bladder, it was necessary to have recourse to catheterism and subsequently to continue it *In the course* of time the urine acquired an effervescent character like that of ginger beer Toruloid cells had reached the interior of the bladder and these acting upon the sugar contained in the urine descending *from the kidney* led *to the occurrence* of alcoholic fermentation I have upon a few occasions in the course of my experience come across this phenomenon, and when once the process is set up it continues whilst the urine remains saccharine, or unless an agent having the power of arresting *fermentation* like, *for instance*, the sodium salicylate be administered. A spontaneous disappear-

to occur in the

sugar was not brought back by a free supply of starchy food In the presence of these circumstances I was afforded the opportunity of personally examining the urine A specimen was sent to me for the purpose and I found it to have a specific gravity of 1008 and to give no reaction of sugar. The ferric-chloride test also gave no reaction, but a trace of albumin, corresponding with what I had noticed before I for awhile lost sight of the patient, was present. After the lapse of a few months I received a notification that death had taken place from general exhaustion.

(To be continued.)

FRACTURE OF THE FIFTH CERVICAL VERTEBRA; RECOVERY.

BY W. E. F. TINLEY, M.D. DURH., M.R.C.S. ENG.,
SURGEON TO THE WHITBY PUBLIC DISPENSARY;

AND

A. R. JONES, M.R.C.S. ENG., L.R.C.P. LOND.

AS recoveries from fracture of the spine in the cervical region are rare the following case may be of interest.

On August 2nd, 1902, a man in the employ of the North-Eastern Railway Company fell from a bridge on to a slope beneath, a distance of 40 feet, and then rolled on to the road below. He was carried home on a ladder and dragged up an awkward staircase on it. As the house was three miles from this town some considerable time elapsed before he was seen, when he was found to be in a semi-conscious condition with almost complete loss of power in the legs, some loss of power in the arms, and complaining of pain in the back of the neck. His pupils were contracted. He had no hæmorrhage from the nose, the ears, or the mouth. He was kept quiet and a sleeping draught was administered. In the evening he was conscious but otherwise his condition was unchanged. On the following morning he had retention of urine and a catheter had to be passed; he was then quite conscious and a fuller examination was possible. There was complete paralysis of the lower limbs with loss of the patellar and superficial reflexes. Well-marked priapism was present. The epigastric, cremasteric, and other superficial reflexes were absent. Respiration was difficult owing to paralysis of the intercostals. The right arm lay in the position of abduction; the elbow was flexed and supinated. The fingers and the wrists were motionless on the right side; this was less so on the left but in a day or two the loss of power was as complete on this side as on the right.

On August 6th the patient began to have incontinence of urine in place of retention and as the nursing was not of the best bedsores began to develop in spite of all care. His temperature during the first few days varied from 101° to 102° F. The most tender spot on the spinal column was over the fifth vertebra, where there was an irregularity, but it was not thought advisable to move the head much to make further examination. The only medicinal treatment was the occasional administration of morphia, chloral, and bromide. He was kept perfectly quiet and his head was steadied with sandbags. He took liquid food fairly well but he had difficulty in swallowing and seemed afraid of "choking." His bedsores got much worse and his general condition became critical and a fatal result seemed to be inevitable unless he could be removed to some place where he could obtain good nursing. He was therefore removed to the Whitby Cottage Hospital three miles away. He was placed on a stretcher and through the window on to a scaffolding that was erected and he was carried by hand to Whitby, placed on a water-bed, and with good nursing the bedsores on the back began to improve but one on the right elbow gave much trouble and remained open till he got out of bed. The arms were flexed and could not be straightened owing to their spastic condition and the fingers were obstinately flexed.

For some months his condition remained very much the same but the superficial reflexes returned and he became extremely hypersensitive; his patellar reflexes were very much exaggerated and he developed ankle clonus. He complained of involuntary contractions of his leg muscles which gave him great pain when they came on. He was able to retain his urine until the urinal was brought but could not retain his fæces until the nurse came to him. About March he began voluntarily to move his feet; later he was able to raise his knees and in June to move his arms a little. The faradic current was used for a short time each day and he had massage for the arms, the fingers, and the legs. He was allowed to sit up in bed in July and was put on a mattress instead of the water-bed and shortly afterwards he was lifted into a chair but could not help himself in any way. In August he was able to take a few steps with help and when he left the hospital in September he walked to a cab but with a distinctly spastic gait. The day before he was discharged the following was found to be his condition. He had good movement at the ankles, the knees, and the hips, and greatly increased knee-jerks; the superficial reflexes were normal; the intercostal muscles still lacked power. He had control over his urine but occasional want of control over his motions. He was able to flex and to extend his fingers to some extent but some of the joints were quite ankylosed. The left shoulder and the elbow were capable of movement to almost the normal extent but his right elbow was nearly fixed at a right angle. He could feed himself and hold a paper to read. The nutrition of the body was fair; that of the skin was good. Over the fifth cervical vertebra was a distinct boss of bone as large as a walnut and he carried his head bent forward and stiff.

When heard of recently the patient's condition was very much the same as when he left hospital. His recovery was to a large extent accounted for by the excellent nursing which he received from the nursing staff at the hospital as he was in a dreadful condition when he reached that institution.

Whitby.

A CONFIRMATORY TEST FOR THE PRESENCE OF MECONIC ACID.

BY F. N. WINDSOR, B.A., M.B., B.C. CANTAB., B SC. VICT.,
CAPTAIN, I.M.S.; OFFICIATING CHEMICAL EXAMINER TO THE GOVERNMENT OF THE PUNJAB.

IN cases of opium poisoning frequently the amount of meconic acid separable from organic matter is so small that it is difficult to determine whether addition of ferric perchloride causes a reddish tint or whether the colour is only yellow. In performing this test a "control" is always carried out with distilled water equal in volume to that of the suspected liquid. This volume is usually about three drachms and test-tubes of small calibre are used to obtain as long a column as possible to look through. Two drops of ferric perchloride solution (B.P.) are added to each tube and the colours are compared. If the reddish tint of the suspected liquid be not distinct then one drachm from the contents of each tube is boiled for 30 seconds. In each case the colour changes to a deep reddish-brown. If to each of the hot solutions four drops of dilute nitric acid (strength 1 in 5) or dilute hydrochloric acid (strength 1 in 7), preferably the former, be added the colour of the ferric meconate solution fades until in 12 hours the solution is colourless while that of the ferric perchloride (in which is a soluble hydroxide) is little or not at all affected.

THE REMOVAL OF KING'S COLLEGE HOSPITAL TO SOUTH LONDON.—The site of 12 acres, at present known as "The Sander's Estate," which has been presented to King's College Hospital in South London, is at the foot of Denmark Hill, close to Camberwell Green, and in close proximity to the three railway stations of Denmark Hill, Loughborough Junction, and Camberwell New Road. In addition to this convenience the main electric tram lines run from Deptford, New Cross, Peckham, right through Camberwell Green, and a further line is now being laid down which will pass the doors of the new hospital, so that the situation is one rapidly and easily accessible from every district of South London. By reason of its position and extent the site affords an opportunity for the building of the most scientifically constructed institution of the kind in England, and it is very earnestly to be hoped that the appeal which is now being made for the £300,000 required to carry out this truly necessary scheme will meet with the hearty support of all generous benefactors throughout the metropolis.

A CASE OF TERATOMA OF THE NECK

BY F BOLTON CARTER, M S , M D LOND , F R C S ENG ,
HOUSE SURGEON TO THE LEICESTER INFIRMARY

THE following case merits publication on account of its rarity The child, a female, was born at full term with a large multilocular semi cystic semi solid tumour of about the size of a small cocoanut occupying the whole of the front of the neck (Fig 1) It caused no trouble during parturition The child only lived one month, the mass being dissected out after death , the hyoid bone was partly included within its structure and most of the muscles of the front of the neck were inserted and lost in the tumour Microscopically it was *seen to consist of glandular spaces lined with epithelium,* cartilage fibrous and connective tissue (Fig 2), and was described by Mr J H Targett of the Clinical Research Association as a true teratoma of the neck

NOTE ON A DICEPHALOUS MONSTER

BY ALEXANDER M ELLIOT, M B , C M EDIN

THE malformation shown in the accompanying illustration may be of interest to some readers of THE LANCET The child was brought to the civil plague hospital in Karachi where I was at the time medical officer in charge It was *most perfectly formed The genital organs, not very clearly* defined in the illustration were quite normal (male) I asked the father if he would part with the child but he would not do so under £50 and eventually the body was buried From what I can gather it was a foot presentation *the right foot coming first The child lived for three hours* The mother made a good recovery

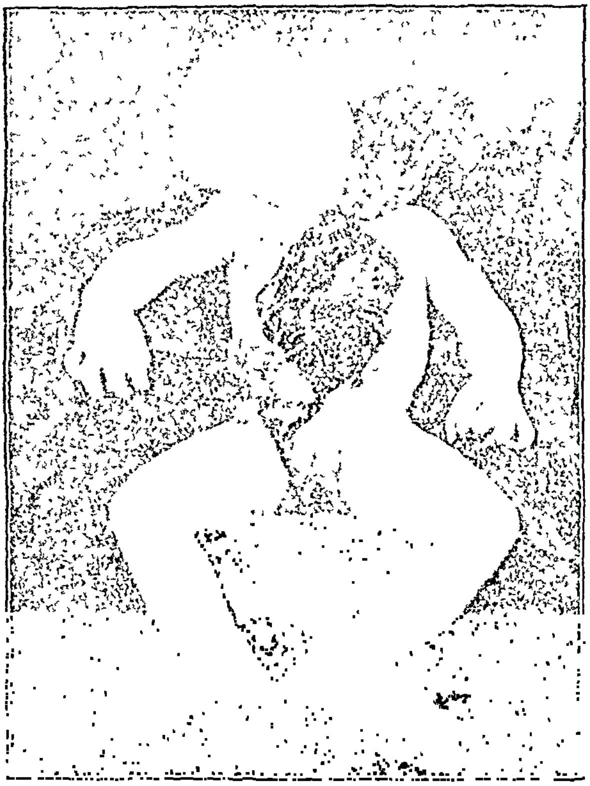
REMARKABLE TRANSPOSITION OF THE VISCERA

BY JOHN C THOMSON M A., M D EDIN

A NEWLY born female child was brought to the public mortuary Hong Kong in 1901 showing a remarkable transposition of the viscera The heart was displaced to the right side, the stomach and the whole of the intestine, excepting the descending colon, occupied the left pleural cavity , and the diaphragm was intact giving passage to the descending colon in the usual position of the œsophagus The lungs, which had not breathed lay behind the viscera named and other abdominal organs occupied their usual positions. The child was well-developed. The illustration shows clearly the stomach in the usual position of the heart and the coils of intestine higher up in the left side of the chest, while the heart appears as a dark body on the right side above the liver.



Transposition of viscera.

GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF ULCERATIVE COLITIS ENDING FATALLY.

(Under the care of Dr. H. W. SYERS.)

A MARRIED woman, aged 29 years, was admitted to the Great Northern Central Hospital on Sept. 6th, 1903. Her health had always been good until about a month before admission. At that time, and without apparent cause, she began to suffer from diarrhœa. There was abdominal pain of a griping character, followed by an imperious necessity to defecate. The motions were at first of a light colour but later became darker, of a chocolate tint. As a rule the bowels had acted as frequently as every two hours. No bright-coloured blood had been observed in the evacuations. As these symptoms continued to trouble the patient she soon began to lose flesh and strength. There had never been any similar illness and the patient had not suffered from enteric fever. She had never been abroad. There was no complaint of cough at any period, either during or before the illness. The family history was quite unimportant. On admission the patient was pale, with a prominent flush on the malar bones; she was very thin and lay in bed on her back with both knees drawn up. The temperature was 100° F., the rate of the pulse was 120, that of respiration being 24. There was no dyspnœa and the pharynx presented a normal appearance. The breath was offensive and the tongue was coated but moist. She complained of eructations, frequent diarrhœa, and of griping pain in the abdomen. The chest was found to be in all respects normal, both as regards the heart and the lungs. The abdomen was distended and tympanitic on percussion. It was generally painful on palpation, the pain not being referred to any special locality. There was no eruption of any kind on the abdomen or elsewhere; the liver and the spleen could not be felt and there was no fluid in the abdominal cavity. No tumour or swelling of any kind could be detected in the cavity of the abdomen. Rectal examination gave a negative result. The motions were of a chocolate colour, were very offensive, and were streaked with bright red blood. The urine was acid and free from albumin and sugar; the specific gravity was 1020. During the first day in hospital the bowels acted five times. On Sept. 10th the abdomen was more distended and was very tender to pressure. The patient complained of severe griping pain. The highest temperature was 101 6°. Sleep was light and broken. Vomiting occurred once only. On the 13th the diarrhœa continued as before, the motions being of a dark-brown colour and quite fluid. No red blood could be detected by the eye but spectroscopic examination revealed the presence of oxyhæmoglobin in the evacuations. The temperature was 102·4°. The patient until this date had taken fluids well but now evinced a repugnancy to all forms of nourishment. The bowels acted five times in the 24 hours. Two days later (the 15th) the temperature was 102·8°. The general condition was less satisfactory, for in spite of treatment the diarrhœa was more frequent, the appetite was very poor, and there was difficulty in getting the patient to take sufficient fluid nourishment. Examination of the abdomen showed less distension and there was less pain on pressure. No mass could be felt. On the 17th the temperature rose to 103·4°. The fever was of a hectic type with an evening rise and a morning fall. The bowels acted ten times in the 24 hours and on one occasion a slough was passed together with a little free blood. There was occasional sickness and the pulse was 144. During the next three days the temperature fell somewhat, being normal on the 20th. At the same time the diarrhœa became rather less frequent. The improvement was, however, of very short duration, for on the 21st the temperature rose to 101·8° and the diarrhœa was again severe, the bowels acting 22 times in the 24 hours. The abdomen continued very tense and was always tender on pressure. Sickness occurred from time to time but was never an urgent symptom. The patient was now in a very debilitated condition though she took food well. On the 26th there was a very marked increase of abdominal pain and tenderness and the expression became somewhat anxious and drawn. Clearly perforation had occurred, for the temperature fell in a few hours from 101·4° to 97° and a distinct fulness, almost a feeling of a mass, could be detected in the right iliac region where the pain and tenderness were most acute. The patient now rapidly lost ground; the teeth became covered with sordes and there was much annoyance from the escape of saliva from the mouth. The temperature did not again rise above 101°; the diarrhœa persisted and the evacuations presented the same character as before. Death ensued from exhaustion on Oct. 4th. That acute general peritonitis had ensued upon the perforation which took place on Sept. 26th was perfectly obvious, though the signs and symptoms of this complication were not marked, as is so often the case when peritonitis supervenes in a patient already worn out with a long and serious illness.

Necropsy.—The post-mortem examination was performed about 24 hours after death. The body was greatly emaciated; rigor mortis was passing off. There was much distension of the abdomen which was tympanitic on percussion. On opening the abdominal cavity a large quantity of very offensive fæcal matter escaped from the wound. The intestines were matted together by acute adhesive peritonitis, which was general and characterised by the presence of flakes of lymph lying on the intestinal coils. A large quantity of fæcal matter was present, the greater portion having found its way into the space between the layers of the great omentum, the latter being converted into a sac containing much of the intestinal contents. The resulting mass was chiefly situated in the right iliac and pubic regions and clearly explained the sensation of fulness to touch, to which reference has already been made in the history of the illness. On separating the coils of intestine it was found that a perforation had occurred of the size of a shilling, the opening being situated in the ascending colon immediately adjacent to the cæcum. The whole of the large intestine was greatly distended with gas, filling the lower portion of the abdominal cavity. The small intestines were in a normal condition save for the presence of slight catarrh, the whole of the abnormal appearances being practically limited to the large bowel. On opening the latter it was found that the whole of the internal surface from the cæcum to the rectum was in a very marked condition of ulceration. Indeed, the mucous membrane was to all intents and purposes destroyed, for it was merely represented by shreds adhering to the surface here and there, these fragments being situated between enormous areas from which the mucous membrane had disappeared altogether, except that in places small fragments still adhered to it in the form of sloughs. The whole surface of the large intestine was of a greyish-black colour. The ulceration did not apparently involve the muscular coat except at the point where perforation had occurred. It may be said, in short, that the whole mucous membrane of the colon was replaced by a vast ulceration, hardly a square inch of healthy membrane being left. The other organs, both abdominal and thoracic, were healthy.

Remarks by Dr. SYERS.—This case is clearly one of those instances of ulcerative colitis which are met with at long intervals and which are by no means easy of explanation as regards their remote and immediate cause. Here we have a woman who had never been out of the country, whose health had always been good, and who without any obvious cause began to suffer from looseness of the bowels of no particular severity, but in whom nevertheless the symptoms presented became rapidly worse and in spite of all treatment in about two months led to a fatal termination. In this instance the most searching inquiry failed to elicit any reason why the patient should have been attacked; there was nothing in her mode of life or surroundings to suggest any definite cause for the malady. It is, of course, very easy to attribute such a case to the ravages of the bacterium coli, but it is scarcely necessary to point out that if the malady were due to the assault of this micro-organism there can be no reason why the disease should not be extremely common, whereas it is by no means frequently met with, being indeed one of the rare intestinal lesions. It is impossible to explain the reason of the occurrence of the malady in this patient and attempts to solve the riddle are merely guesses at truth. Practically every kind of treatment likely to be of use in controlling the disease was employed and one and all failed completely. The ordinary astringents, with bismuth and opium, failed to exert any influence upon the constant diarrhœa; the only drug which had the least effect was nitrate of silver. This was given by the mouth and also injected per rectum A trifling alleviation followed the administration of the remedy but in no long time even this slightly favourable effect was lost. A few days before death it was perfectly obvious that perforation had occurred, for there was marked increase of abdominal pain and tenderness at the same time that a distinct swelling appeared in the right iliac region. This swelling was irregular in shape and somewhat indefinite in outline; it was clearly due to the extravasation of the contents of the large intestine found post mortem. Although it was perfectly certain that perforation had occurred the question of the necessity of laparotomy did not of course arise, as no good result could have been anticipated from surgical intervention The post-mortem findings entirely confirmed the accuracy of this view of the matter. It must be admitted that in this malady, which certainly deserves to be classified as a separate and distinct affection with well-defined symptoms and morbid appearances, no kind of treatment is of any avail and it must unfortunately be regarded as an inevitably fatal disease. Luckily such cases are distinctly uncommon and on this account only it is important that every well-observed instance in which a post mortem examination has been made should be put on record. To Mr G A. Upcott Gill and to Mr. A. de Morgan, house physicians, I return my thanks, being indebted to them for the notes of the case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

50 Consecutive Cases of Perforated Gastric and Duodenal Ulcer treated by Laparotomy.

A MEETING of this society was held on Nov. 24th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. T. CRISP ENGLISH read a paper based upon 50 consecutive cases of Perforated Gastric and Duodenal Ulcer treated by Laparotomy at St. George's Hospital, the majority of which he had had the opportunity of observing and taking notes upon The value of hospital statistics was referred to. Acute perforations only were dealt with; of these, 42 occurred in gastric ulcers, 22 of the patients recovering; and eight in duodenal ulcers, with two recoveries. The question of premonitory symptoms was dealt with. These were found to occur in 20 per cent of the cases and conclusions were drawn from an analysis of these cases. The occurrence of a "quiescent period" after the primary collapse was discussed and illustrative cases were quoted. The frequency of vomiting, the condition of the hepatic dulness, and the situations of the perforation were next referred to. The incidence of complications after operation was analysed. Complications occurred in 13 of the 24 successful cases and in eight of the fatal cases which survived the first 24 hours after operation. Parotitis, pleurisy, thrombosis, hæmatemesis, and other conditions were referred to. Such cases were quoted presenting the symptoms and signs of perforation which was proved by laparotomy not to have occurred. Various details in the operation were referred to. The increasing tendency to dispense with drainage was mentioned. In order to ascertain the after-condition of the patients 17 of the 24 successful cases had been followed up The results of this investigation were given: in 12 cases there had been no return of gastric symptoms, four had had slight dyspepsia readily amenable to medical treatment, and one was troubled with symptoms of extensive peritoneal adhesions.

Mr G R. TURNER said that seven of the cases referred to in Mr. English's paper had been under his care He had used drainage in all of these cases and he had drained the kidney region, Douglas's pouch, and also in some cases the seat of the perforation He considered that it had been beneficial in all his cases Two of the seven cases had died; the first was an almost hopeless case at the time of the operation and died shortly after the operation was completed. The second had on admission acute peritonitis and that case also died shortly after operation. The five cases in which recovery occurred were females and in two of them thrombosis of the veins of the left leg had taken place. He always stitched up the ulcer as soon as possible so as to prevent any further extravasation of stomach contents into the peritoneal cavity and after that was done he put in the Lembert's sutures and tucked in the ulcer. In one case he had opened the abdomen and found absolutely nothing abnormal. This was a case of pure neurosis simulating organic disease In another case of ruptured œsophagus the symptoms exactly resembled those which occurred in perforation of a gastric ulcer

Mr. J WARRINGTON HAWARD said that hospital statistics were of special value as they were unselected and included the unsuccessful as well as the successful cases. He thought that, as a rule, the symptoms of perforation were sudden in onset and they came on more frequently after food than after exertion In cases, however, in which adhesions were present it was not unusual for perforation of a gastric ulcer to occur after exertion. The situation of the pain gave no hint as to the point where the perforation had taken place, but if the case was seen before perforation had occurred then the superficial tenderness was of diagnostic value. He thought that the frequency of the pulse-rate was [illegible] and if the pulse-rate [illegible] that an operation [illegible] that the pleurisy which so frequently occurred was due to the passage of septic material by means of the lymphatics passing through the diaphragm to the pleura. He considered that drainage was advisable in those cases in which a considerable period had elapsed after the perforation had taken place.

Dr. J. F. H. **BROADBENT** mentioned two cases of traumatic rupture of the duodenum. The first was that of a child who fell across a chair. No immediate symptoms were produced. Shortly after this she took a glass of milk and had severe pain in the abdomen with obvious symptoms of perforation. The child died and it was found that there was a rupture of the third part of the duodenum. The second case was that of a man across whose abdomen a ladder fell. There were no immediate symptoms but on the following day the patient complained of pain in the right iliac fossa. The abdomen was opened in this region but no perforation could be found. A week later he suddenly had signs of acute peritonitis and died. It was found that the duodenum had been ruptured posteriorly and that an abscess had formed behind the peritoneum. The abscess had ruptured and given rise to the acute symptoms. He thought that duodenal ulcers usually occurred in men in good health and that the "quiescent period" was likely to be more marked than in cases of perforation of gastric ulcer.

Dr. H. S. **FRENCH** asked what was the cause of the parotitis in these cases and whether it had been less frequent since attention had been paid to the mouth. In dealing with the diagnosis of the perforation no mention had been made of locomotor ataxia. He referred to a case of locomotor ataxia in which perforation of a gastric ulcer had occurred. He mentioned cases of dissecting aneurysm and thrombosis of the superior vena cava which had simulated perforation of a gastric ulcer. He doubted whether the after-results of operation were always so favourable as those mentioned in the paper. In one case a man had suffered from severe pain after operation for nearly two years.

Mr. C. R. B. **KEETLEY** said that since 1899 he had operated on nine cases of perforated gastric ulcer; six patients had recovered and three had died; the six who recovered had been operated on within 30 hours, while the three who died were not operated on for three or four days after the perforation. In one of the fatal cases a second perforation was found and in another profuse hæmorrhage occurred and the patient died in a few hours. With regard to the advisability of performing a gastro-enterostomy he did not think that it was needed in most cases but it might have prevented the fatal result which had occurred in his second case from hæmorrhage.

Dr. G **NEWTON PITT** said that he had seen several cases of perforation of gastric ulcer operated on and thought that irrigation of the peritoneum was unnecessary; much, however, depended on the virulence of the fluid in the peritoneum He thought that the "quiescent period" was dependent upon the fact that owing to absence of movement of the diaphragm the pumping action in the lymphatics was not maintained and the toxic substances from the abdominal cavity were not conveyed into the general circulation. He suggested that the examination of the blood might be of some value in distinguishing the cases of pure neurosis from those of actual perforation.

Dr. S **VERE PEARSON** referred to the frequency of diminution of liver dulness which he had found to be present in about one-third of all cases admitted for hæmatemesis. The condition could not be explained by general distension of the intestine nor was it due to a dilated stomach. He thought the most likely explanation was that it was due to a dilated colon, though even this explanation was hardly adequate

Mr. H. J. **PATERSON** said that he was adverse to irrigation and even mopping of the peritoneum. He was in favour of using simple gauze drainage. He believed parotitis to be due to the dry condition of the mouth and since he had used an antiseptic mouth wash he had not seen that complication occur. Three reasons had been given by Mr English for not performing a gastro-enterostomy: (1) that it increased the length of the operation; (2) that it increased the risk; and (3) that it was unnecessary. He, however, could not agree with these reasons and considered that gastro-enterostomy was of advantage, first, because it gave the stomach physiological rest; secondly, because it facilitated the healing of other ulcers, if present, in the stomach; and thirdly, because it was possible to feed the patient earlier.

Mr. T. **CLINTON DENT** said that there were two points with which he would deal: first, he was of the opinion that the less irrigation was used the better; and secondly, he considered that gastro-enterostomy was unnecessary and did not fulfil the objects stated by the last speaker. He considered it of special importance to feed patients at an early period after the perforated gastric ulcer had been closed.

Mr. **ENGLISH** replied.

MEDICAL SOCIETY OF LONDON.

The Treatment of Cardiac Failure.

A MEETING of this society was held on Nov. 23rd, Dr. F. DE HAVILLAND HALL, the President, being in the chair.
